*lusi* inhabits the sandy plains of Africa and Arabia, and is the largest of all existing birds, attaining a height of from 6 to 8 feet. The head and neck are nearly naked, and the quill feathers of the wings and tail have their barbs wholly disconnected. It is chiefly for these plumes, which are highly esteemed as articles of dress and decoration, that the bird is hunted and also reared in domestication. The legs are extremely strong, the thighs are naked, and the tarsi are covered with scales. There are only two toes, the first and second being wanting. The pelvic bones are united, a conformation occurring in no other bird. The wings are of small size and incapable of being used as organs of flight; the birds can run with extraordinary speed, distancing the fleetest horse. The food consists of grass, grain, and other substances of a vegetable nature. Ostriches are polygamous, every male consorting with several females, and they generally keep together in larger or smaller flocks. The eggs are of great size, averaging three pounds each in weight, and several hens often lay in the same nest, which is merely a hole scraped in the sand. The

eggs appear to be hatched mainly by incubation, both parents relieving each other in the task, but also partly by the heat of the sun. The South African ostrich is often considered as a distinct species under the name of *S. australis*. Three South American birds of the genus *Ehea* are popularly known as the *American ostrich*, though they are not very closely allied to the true ostrich, differing in having three-toed feet and in many other respects. The best-known of the three is *E. americana*, the *mandu* or *manduquaca* of the Brazilians, inhabiting the great American pampas south of the equator. It is considerably smaller than the true ostrich, and its plumage is much inferior. *E. darwini*, a native of Patagonia, is still smaller, and belongs to a different subgenus (*Ptilocnemis*). The third species is the *E. macrorhynchos*, so called from its long bill; it is perhaps only a variety of the first.

**Otolith** (ô'tô-lith), *n.* [*Otiç* (*ôtiç*), ear, + *lithos*, stone.] 1. A calcareous concretion within the membranous labyrinth of the ear. In fishes and fish-like vertebrates they are sometimes of great size. In higher animals otoliths are generally wanting or reduced to small particles or ear-dust. (See *otoconium*.) Among some common fishes the otolith decreases in size in the following order: cod, hake, haddock, whiting, conger, turbot, sole, gurnard, smelt, and trout. The concretions differ much in shape. In the conger the otolith is shaped like a sole, 1 1/2 inches long, 3/4 inch wide, and is thin and glassy. In the cod it is of the size of a horse-bean, and is curved on itself. The ear-stones of the American sheephead are shaped like a tamarind-seed, and look like pieces of milky quartz. They are often carried in the pocket as "lucky stones."

They have properly no part in the bony structure of the ear, but a vibratory or concussive function in audition. But *otolith* and *otosteon* are sometimes applied to the internal ear-bones of fishes.

Down thirty feet below the smiling day.

*Tennyson*, *Harold*, ii. 2.

Oubliettes are common in old eastern houses, as in the medieval castles of Europe, and many a stranger has met his death in them. They are often so well concealed that even the modern inmates are not aware of their existence.

The British fluid ounce is equal to 28.4 cubic centimeters, and that of the United States to 29.57 cubic centimeters.

**-ous**. [ME. *-ous*, *-ouse*; < OF. *-ous*, *-os*, *-us*, *-us*, later *-our*, *-our* = Sp. Pg. *-oso*, < L. *-osus*, for *\*-ousus*, orig. (Aryan) *\*-wansa*, *\*-wanta*, a suffix (equivalent to E. *-ful* or *-y* or *-ed*) attached to nouns to form adjectives noting fullness, as in *callosus*, hard-skinned, callous, *famosus*, noted, famous, *gigerosus*, well-horn, generous, *odiosus*, hateful, *odious*, *religiosus*, scrupulous, religious, *sumptuosus*, costly, sumptuous, *rituosus*, faulty, vicious, etc.] A suffix of Latin origin, forming, from nouns, adjectives denoting fullness or abundance, or sometimes merely the presence, of the thing or quality expressed by the noun, as in *callosus*, *famosus*,

*gigerosus*, *odiosus*, *religiosus*, *sumptuosus*, *vicious*, etc. (see *etymology*). Many modern English adjectives taken directly from the Latin have *-ose*, as *jucose*, *verbosus*, with or without an equivalent form in *-ous*, as *herbous*, *herbous*, *ourous*, *ourous*, *ourous*, *ourous*, etc., the form in *-ose* being especially common in botanical terms. By reason of the agreement in the terminal pronunciation of English adjectives in *-ous* and the English pronunciation of Latin adjectives in *-us* (in Latin a mere nominative termination), many such adjectives in *-us* have been transferred into English with the accommodated termination *-ous*, as *univirsus*, *conspicuous*, *devotus*, *obscurus*, *precious*, *serius*, etc., from Latin *univirsus*, *conspicuosus*, *devotus*, *obscurus*, *preciosus*, *serius*, etc. So with Latin or New Latin adjectives in *-us* from Greek *-os*, as in *accephalous*, etc. The suffix *-ous* is felt as an English formative only when a noun accompanies the adjective, as in *famous*, *odious*, *religious*, *unobvious*, etc., associated with the nouns *fame*, *odium*, *religion*, *ambition*, etc. It is sometimes used (as also *-ose*), as an English formative, attached to words of non-Latin origin, as in *quartzous* or *quartzose*, etc.

**ouset**, *n.* An obsolete form of *ooze*.

**outcrop** (out-'krop), *n.* The appearing at the surface of a stratum or series of strata, or of a vein or ore-deposit of any kind. This is called by Cornish miners the *brail*. The outcrops of many veins, on the other hand, are very conspicuous, especially when the amount of ore present is small, quartz forming the predominating vein-stone of a large proportion of the mineral deposits, and being very indestructible. The outcrops of the stratified formations depend on the amount of inclination of the beds. When these lie quite horizontal, there can be no outcropping edges of the strata, except when the formation has been cut into by erosion. The position on the surface of any outcrop depends, therefore, on the inclination of the bed or vein in question, and on the nature and amount of the erosion which has taken place. That part of a female animal in which ova, eggs, or germs are generated and matured; the essential female organ of reproduction, corresponding to the testes of the male; the female genital gland or germ-gland; the ovarium. In vertebrates the ovary is a glandular organ, usually paired, sometimes single, and morphologically identical with the testes, both these organs being developed from a primitively indifferent genital gland common to both sexes; the differentiation of this structure into ovary or testes being the fundamental distinction of sex upon which all other sexual differences are consequent. The ovary consists of its proper stroma or tissue peculiar to itself, in which the ova are produced, bound up in ordinary connective tissue, supplied with appropriate vessels or nerves, and fixed in the abdominal cavity by means of a mesentery. With the ovary is usually but not always associated a special structure, the *oviduct*, serving to convey away the eggs. The ovary is relatively largest in those animals which lay multitudinous eggs, as fishes, in which it is known as the *roe*. It is also large in oviparous animals which lay large meroblastic eggs with copious food-yolks, as birds and most reptiles. It is very small in mammals. The ovary in woman is a flattened ovoid body about 1½ inches long, 1 inch wide, and ½ inch thick, resting on the broad ligament of the uterus and closely connected both with that organ and with the Fallopian tube or oviduct. Among invertebrates in which there is distinction of sex, the name *ovary* is applied to any part of the body which can be recognized as having the function of ovulation. Such organs are of almost endlessly varied character in all but the one essential physiological respect. Several kinds of ovaries receive specific names; and in many cases the analogy to

*a*, posterior abdominal ganglion; *b*, *b*, right and left ovarioles, formed by union of *c*, *d*, *e*, the ovarian tubes or ovarioles; *f*, filament by which ovarioles of opposite sides are united; *g*, spermatheca; *h*, *h*, the colleterial glands, or colleterium.

the part of a plant called the ovary (see def. 2) is striking. See cuts under *Dibranthia* and *Nematodea*.

2. In bot., a closed case or receptacle, the lower section of the pistil, inclosing the ovules or young seeds, and ultimately becoming the fruit. Structurally the ovary is a modified leaf which is folded involutely so as to form a cavity, and with the style and stigma it constitutes the female sexual organs (gynoecium) of flowering plants. The ovary may be simple (that is, composed of a single leaf), or compounded of two or more leaves. The modified part of the interior of the ovary which bears the ovules is called the *placenta* (which see). The phrases *superior* and *inferior* ovary are used to designate the position of the ovary in relation to that of the floral envelopes: thus, *ovary superior* is that in which the other parts of the flower are inserted upon the axis below the ovary; *ovary inferior* is that in which the other parts of the flower are inserted above, seemingly upon the ovary. See cuts under *anthophore*, *Aracea*, *Didymaria*, *dimerous*, and *myrtle*.

1. A chamber or receptacle in which food is cooked by the heat radiated from the walls, roof, or floor. (a) A chamber built of brick, tiles, or the like, and usually heated by fuel which is allowed to burn away before the food is introduced, the cooking being done by the heat retained. (b) A chamber for baking or cooking in a cooking-stove, range, or furnace, the heat being usually transmitted through one or more of the sides.

In stead of bread they die a kind of fish which they beat in mortars to powder, and bake it in their *ovens*, until it be hard and drie.

*Holmsted, Descrip. of Britain, i. x.*

2. In general, any inclosed chamber adapted to or used for applying heat to raw materials or to articles in process of manufacture. The heat so applied may be radiated from the previously or continuously heated walls of the inclosure, or it may be derived from currents of heated air or gases or superheated vapors circulated through the oven, from interior or exterior coils of pipes heated by steam or hot water, or from the solar rays. The name *oven* is given to a great variety of structures and devices employed in domestic industry, in chemical operations, and in the mechanical arts. Specifically—(a) A kiln. (b) A muffle-furnace. (c) A lehr.

3f. A furnace.

The king's servants, that put them in, ceased not to make the *oven* hot with rosin, pitch, tow, and small wood; so that the flame streamed forth above the furnace forty and nine cubits.

*Song of the Three Holy Children (Apocrypha), v. 23.*

4. An oven-bird or its nest.—**Air-oven**, an oven in which baking or drying is done by circulating heated air through it. It is much used in laboratories and in the arts. In some cases, as in drying gelatin plates for photography, the air is filtered on its way to the oven by passing it through cotton-wool. In air-ovens the air may be heated prior to its admission, or by interior heating appliances.—**Annealing-oven**, an oven used for annealing, as the lehr of glass-manufactories for slowly cooling glass, which, if cooled rapidly, would be exceedingly brittle; or, as in the manufacture of malleable iron-castings, the inclosure in which the articles, after casting, are treated to render them malleable.—**Bakers' oven**, an oven used by bakers in baking bread, biscuits, crackers, and other articles of food. The principal oven still in use by bakers is a brick reverberatory oven with an arched roof; but in the manufacture of biscuits, crackers, wafers, etc., on a large scale, reel-ovens and rotary-ovens are used.—**Beehive oven**. See *beehive*. **Brick oven**, an oven constructed of brick, in contradistinction to an oven made of metal or other material. Brick ovens usually apply their heat from their walls previously heated by an interior fire, which is withdrawn prior to putting in the article to be baked. Such an oven for domestic use was once very common in dwellings, and was generally built at the side of or in close proximity to the chimney then in use. It often projected from the exterior of the building, and this construction is still to be seen in many old country houses. It has a smoke-uptake in the upper part of the mouth and a flue leading from the uptake, and connects at its upper end with the fireplace chimney. Wood is the fuel used, and when the fire is kindled the air draws into the mouth and passes over the bottom of the oven, while the heated gases of combustion rise to the top and pass forward to the uptake. **Bush-oven**, the long-tailed titmouse or oven-bird, *Arreola rosea*. [*Norfolk, Eng.*]—**Drying-oven**, an oven used for expelling moisture from substances or textures. The air-oven is the most generally used of this class. Drying-ovens heated to a point somewhat above the boiling-point of water, which expel water by converting it into steam, are also used for many purposes.—**Dutch oven**, a tin utensil for roasting meat, etc., closed at the sides, back, top, and bottom, and somewhat resembling in shape an open shed. The oven covers the joint or other article to be roasted on all sides except that facing the fire. (Also called *kitchen* or *tin kitchen* in the New England States and elsewhere.) The bake-kettle, a cast-iron vessel with a close-fitting convex cover upon which hot embers or coals are placed when the implement is used, is also sometimes called a *Dutch oven*.—**Egyptian oven**, a large earthen crock sunk in the ground, and heated by interior fire, which is removed to permit the baking of lumps of dough. These are thrown with force against the interior, and adhere thereto. The crock is then covered till the baking is finished. This is a very ancient form of oven, largely used in the East even to the present day.—**Elevated oven**, a range-oven situated higher than the fire-pot.—**Heating-oven**, an oven designed or used for simple heating, as in heating pieces of wood or other materials to be joined by glue or cement, or for heating vessels that must be used while hot; a hot-closet.—**Out-oven**, a domestic brick oven built by itself, apart from any building. Its construction is almost identical with that

described under *brick oven*, except that it has a chimney extending straight upward over the mouth of the oven.

**Reel oven**, an oven in which the substances to be baked or dried are placed on swinging shelves attached to endless chains running on reels within a heated inclosure. The reels are turned at a velocity that permits the articles to be dried sufficiently, or baked completely, when the chain makes a complete circuit, which brings one of the swinging shelves on a level with the door of the oven. The finished articles are then removed from this shelf, and a new charge is put in their place. This discharging and recharging is successively performed for each shelf. Generally, ovens of this kind and rotary ovens are continuously heated by circulation of heated air through them, or by heated air through their walls, or by highly heated steam-coils.

**Revolving oven**, an oven in which the floor, or the shelves supporting the articles to be baked, etc., revolve horizontally or vertically. The articles are completely dried or baked in a single revolution, and are successively removed or replaced by new charges, as described under *reel oven*, which is an example of this kind of oven. In some ovens of this class a shaft with radial arms carrying swinging shelves rotates vertically in the heated inclosure. The manipulation and heating are as described under *reel oven*.

**Rotary-hearth oven**, an oven in which the floor or hearth revolves.—**Rotary oven**, an oven which can be horizontally rotated as a whole on a central pivot. Such ovens were formerly used with a form of kitchen stove called *rotary stove*. They were portable tin ovens made to fit the tops of the stoves, which were circular, and constructed to rotate on a central pivot. The top of the stove was toothed on the under side of its outer margin. The teeth were engaged by a small pinion operated by a crank. The articles to be baked were placed on the top of the stove, and covered with the portable tin oven, and, to prevent overheating of any part, the top of the stove was frequently turned to change the position of the parts relatively to the fire-pot.

**Traveling-apron oven**, an oven in which an endless belt traverses horizontally, carrying the articles to be baked from end to end of the oven. (See also *cake-oven*, *porcelain-oven*, *roasting-oven*, and *tile-oven*.)

**oven-bird** (uv'n-bîrd), *n.* 1. The golden-crowned thrush, *Sturnus auricapillus*, an oscine passerine bird of the family *Mniotiltidae*; so called from the fact that its nest is arched or roofed over like an oven. [Local, U. S.]—2. Any bird of the South American family *Furnariidae*, which builds a domed or oven-like nest. See cut under *Furnarius*.—3. The long-tailed titmouse, *Arreola rosea*. [Prov. Eng.]—4. The willow-warbler, *Phylloscopus trochilus*. Also called *ground-oven* and *oven-tit*. [Prov. Eng.]

**oven-builder** (uv'n-bîl dër), *n.* The oven-bird *Arreola rosea*.

Its form varies from a brief flourish to a medley of melodies or themes extracted from the body of the work, or to a composition of independent form complete in itself. In some cases overtures are divided into two or more sections or movements, resembling those of a suite or a symphony, each modeled upon some dance form, the sonata form, the fugue form, etc.; but they are more frequently in a single continuous movement. Many veritable overtures being successfully used as concert pieces, it is now customary to give the name to detached works for orchestra which are intended simply for concert use, though in such cases a special title is usually given to the composition.

Specifically—6. *Eccles.*, in Presbyterian church law, a formal proposal submitted to an ecclesiastical court. An overture may proceed either from an inferior court or from one or more members of the court to which it is presented. In the General Assembly of the Church of Scotland (as in the supreme courts of most Presbyterian churches) legislative action is initiated by adopting an overture and sending it to presbyteries for their consideration. See the quotation.

Before the General Assembly passes any Acts which are to be binding rules and constitutions to the Church, . . . the same must be first proposed as an *overture* to the Assembly, and, being passed by them as such, be remitted to the consideration of the several Presbyteries of this Church, and their opinions and consent reported to the next General Assembly. . . . If returns . . . show that a majority of the Presbyteries approve, the *overture* as sent down may then be passed, and most frequently is passed, into an Act by the Assembly.

**oviduct** (ô-vi-duk't), *n.* [*< NL. oviductus, < L. ovum, egg, + ductus, a leading, duct; see duct*.] The excretory duct of the female genital gland, or female gonaduct; a passage for the ovum or egg from the ovary of an animal; chiefly applied to such a structure in an oviparous animal, not differentiated into Fallopian tube, womb, and vagina. An oviduct exists in most vertebrates, and is usually paired, there being one to each ovary, but often single, the duct of one or the other side remaining undeveloped, as in birds. When well formed, as in birds and other animals which lay large eggs to be hatched outside the body, the oviduct is a musclemembranous tube or canal, of which one end is in relation with or applied to the ovary, and the other debouches in the cloaca, the tube being held in place by a special mesentery or mesometrium. In the course of the oviduct its mucous membrane acquires special characteristics, and secretes different substances; so that the ovum, escaping from the ovary as a ball of yellow yolk, becomes successively coated with white albumen, with a soft egg-pod, and finally, as in birds, with a hard chalky shell. The oviducts of the lowest mammals, which are oviparous, are of similar character; but in most mammals the pair of oviducts coalesce in the greater part of their length, whence result a single vagina and womb, with a pair of Fallopian tubes or oviducts in a restricted sense. A womb or uterus is simply a specialized part of an oviduct, where the ovum is detained long enough to be developed into a fetus and born alive. The oviducts of invertebrates, where any exist, are as diverse in character as the ovaries. See *ovary*, and cuts under *Dendrocaela*, *Dibranchiata*, *Epizoa*, and *germarium*.

It normally consists of three pairs of rhabdites, the outer two pairs of which incise or sheathe the inner pair, and form an extensible tube, of

very variable size and shape in different insects. It is sometimes longer than the body of the insect. In the tercolant hymenoptera the ovipositor forms a saw, or an auger (serra or terabra). In the aculeate hymenoptera, as bees and wasps, the ovipositor is the sting or aculeus. In orthoptera it is often conspicuous, as seen in the cut. Also called *oviscap*. It occurs in some fishes, many reptiles, some insects, as flesh flies, various worms, and a great many other invertebrates. The carrying of eggs in any special receptacle about the body, from the time they leave the ovary until they hatch, also constitutes ovoviviparity. **ovulation** (ô-vû-lâ'shôn), *n.* [*< ovulate*, *v.*, + *-ion*.] The formation or production of ova or ovules; also, a discharge of an ovum from the ovary. In women ovulation normally recurs thirteen times a year during the sexual life of the individual, and is accompanied by the phenomena of menstruation.

**ovule** (ô'vûl), *n.* [*< F. ovule*, *< ML. ovulum*, a little egg (*NL.* an ovule), dim. of *L. ovum*, egg; see *ovum*.] **1.** A little egg; specifically, in *anat.*, *physiol.*, and *zool.*, an ovulum or ovum, especially a small one, as that of a mammal, or one not yet matured and discharged from the ovary; specifically applied by Haeckel to the ovum or fertilizable but unfertilized egg-cell of the female, conformable with the use of *spermule* for the male sperm-cell. Its protoplasm is termed by him *ovoplasm*, and its nucleus *ovococcus*.—**2.** In *bot.*, a young or rudimentary seed; a peculiar outgrowth or production of the carpel which, upon fertilization and the formation of an embryo within, becomes the seed. In the angiospermous gynoecium the ovules are normally produced along the margins or some part of the margins of the carpellary leaf, either immediately or by the intermediation of a placenta, which is a more or less evident development of the leaf-margins for the support of the ovules. Rarely ovules are developed from the whole internal surface of the ovary, or from various parts of it, in no definite order, directly from the walls, and without the intervention of anything which can be regarded as a placenta. In gymnosperms the ovules are borne on the face of the carpellary scale or at its base; or on metamorphosed leaf-margins, as in *Gnetum*; or when there is no representative of the carpel on the cauline axis, seemingly as a direct growth of it, (*Gnetum*). The only essential part of the ovule is its *nuculus* or *ovoid*, as it has been termed recently, which is usually invested by one or two coats, the *pericarp* and *sarcotesta*. The coats are sacs with a narrow orifice called the *micropyle*, the closed vestige of which becomes the *micropyle* in the seed. The proper base of the ovule is the *chalaz*, and it may be either sessile or on a stalk (stipule) of its own. The *hilum* is the scar left when the seed is detached from its funiculus. As to shape ovules may be orthotropous, campylotropous, amphitropous, or anitropous; and as to position in the ovary, they may be erect, ascending, horizontal, pendulous, or suspended. In regard to numbers they may be solitary, few, or indistinctly numerous. See cuts under *acumbent*, *anatropous*, *funicle*, *macula*, *orthotropous*, and *ovary*.

**ovum** (ô-vum), *n.*; *pl.* *ova* (ô-vû). [*L.* = *Gr.* *ovon*, an egg; see *egg*.] 1. An egg, in a broad biological sense; the proper product of an ovary; the female germ or seed, which when fertilized by the male sperm, and sometimes without such fecundation, is capable of developing into an individual like the parent. There is a great similarity in the ova of different animals throughout the metazoic series, from the sponge to the human being, no ova in their early stages being distinguishable from one another in their essential characters. All true ova, as distinguished from spores and products of fission or gemmation, are referable to the single morphological type of the *ovul*; and they are furthermore indistinguishable from unicellular animals, and from many of the cells composing the bodies of the higher animals. An ovum consists of a quantity of protoplasm or cell substance called the *vitellus* or *yolk*, inclosed in a cell-wall or vitelline membrane, and provided with a nucleus and usually a nucleolus; it is engendered in the ovary, usually in an ovicel or so-called Graafian follicle, is discharged from its matrix, usually then meeting with the male element, and proceeds to develop within or without the body of the parent. The ovum proper, like most cells, is usually of microscopic size; but its bulk may be enormously increased by the addition of extrinsic or adventitious protoplasmic or albuminous substance, and it may be further protected by various kinds of egg-pod or egg-shell, all without losing its essential character as a cell. The largest ova, relatively and absolutely, are birds' eggs, these being by far the largest cells known in the animal kingdom. Here the quantity of food-yolk which does not undergo transformation into the body of the chick is out of all proportion to the formative yolk proper, which makes only a speck in the great hall of "yellow" and "white." Such ova are called *macroblastic*, in distinction from *microblastic*. The human ovum is very minute, relatively and absolutely, averaging about  $\frac{1}{100}$  of an inch in diameter. It is said to have been first recognized by K. E. von Baer in 1827. The parts of the ovum have been badly named, without reference to its morphology as a cell. Thus, the cell wall is called the *zona pellucida*; the nucleus is named the *germinal vesicle* or *vesicle of Purkinje*, and its nucleolus the *germinal spot* or *spot of Wagner*. The phrases *germinal vesicle* and *germinal spot* are misleading. The first stages of development of an ovum, consequent upon fertilization, consist in the segmentation of the *vitellus*, or yolk division, by which the cell-substance becomes a multicellular mass of spherules, called the *morula*. The rest is an intricate process of differentiation and specialization of these spherules, and their multiplications into the myriads of different kinds of cells of which the whole body of most adult animals is fabricated. Some of the early special stages of this process are known as the *morula*, *gastrula*, *blastula*, etc. The first tissue or coherent layer of cells produced is called a *blastoderm*. When there are two layers, inner and outer blastodermic layers, they are distinguished as *emboderm* and *ectoderm*; when a third intermediate layer is formed, it is the *mesoderm*. An ovum is called, in general, a *germ* until the rudiments of its specific characters appear, when it becomes an *embryo*, and later may be a *fetus*. That department of ontology which treats of the development of the ovum is *embryology*. See

A rapacious nocturnal bird of prey of the family *Strigidae*. Owls constitute a highly monomorphic group, the suborder *Striges* of the order *Raptores*. With few exceptions, they are of distinctively nocturnal habits and a peculiar physiognomy produced by the great size and breadth of the head and the shortened face with large eyes looking forward and usually set in a facial ruff or disk of modified feathers, which hide the base of the bill. Many owls have also "horns" (that is, ear tufts) or plumicorns. The bill is hooked, but never toothed, and the nostrils open at the edge of the cere, not in it. The plumage is very soft and blended, without shafts, and the flight is noiseless. The talons are large, sharp, and hooked as in other birds of prey; the outer toe is versatile, and the feet are usually feathered to the claws. (See *ent under hircate*.) There are many anatomical characters. (See *Striges*.) Owls are among the most nearly cosmopolitan of birds. They feed entirely upon animal substances, and capture their prey alive, as small quadrupeds and birds, various reptiles, fishes, and insects. They lay

from three to six white eggs of subspherical shape. There are about 200 species, assigned to some 50 modern genera, and now usually considered as constituting 2 families, *Aluco* and *Strigidae*, or barn-owls and other owls. See cuts under *barn-owl*, *Bubo*, *Glauclaudium*, *huck-owl*, *Nyctale*, *Otus*, *snow-owl*, and *Strix*.

2. A variety of the domestic pigeon: so called from its owl-like physiognomy. The head is round, and the beak very short. There are several strains of owls, known as English, African, and Chinese. All run in various colors.

The *owls* are African, English, and Chinese. The African is at home in Tunis, whence many thousands have been sent to England, and of which scarcely dozens remain. The bird is the smallest of the family, and so delicate that its term of life out of African air is very limited. The English *owl* is fair in size, with eye round and prominent, the dewlap well developed, and the bill extending to the lower point of the breast. In the Chinese this bill-feathering is excessive, even extending up about the throat to the eyes.

The Century, XXXII, 107.

in the natural state as a *bull*, whose female is a *cow*, and whose young is a *calf*; in a wider sense, an animal of the family *Bovidae* and subfamily *Bovinae* or *Oribovinae*; a bovine. The several animals of this kind have each of them specific designations, as *buffalo, bison, aurochs, zebu, musk-ox*, etc.; the word is commonly restricted to the varieties of *Bos taurus*, the common ox, which is one of the most valuable of domestic animals. Its flesh is the principal article of animal food, and there is scarcely any part of the animal that is not useful to mankind; the skin, the horns, the bones, the blood, the hair, and the refuse of all these, have their separate uses. Having been specially domesticated by man from a stock which it is probably impossible to trace, the result has been the formation of very many breeds, races, or permanent varieties, some of which are valued for their flesh and hides, some for the richness and abundance of their milk, while others are in great repute for both beef and milk. Among the first class may be mentioned the Durham or shorthorn, the polled Aberdeen or Angus, and the West Highland or kyloe. Among the most celebrated for dairy purposes are the Jersey, Guernsey, Holstein-Friesian, Ayrshire, and Suffolk dun. For the purposes both of the dairy-farmer and of the grazier, the Hereford and a cross between a shorthorn and an Ayrshire are much fancied. The ox is used in many parts of the world as a beast of draft. The "wild ox," now surviving in only a few parks, as at Chillingham Park in Northumberland, and at Cadzow Forest in Lanarkshire, seems, whatever its origin, to have been formerly an inhabitant of many forest-districts in Great Britain, particularly in the north of England and the south of Scotland.

The characteristic leaves are of three radiating inversely heart-shaped leaflets; others are pinnate or undivided. The flowers are yellow, pink, or white, usually in long-stalked umbels, with additional minute

An element discovered by Priestley in 1774, who called it *dephlogisticated air*. It was finally called *oxygen* by Lavoisier, because supposed to be present in all acids. Further investigation, however, has proved that this is not the case. Oxygen is a chemical element existing as a permanent gas, colorless, odorless, and tasteless, and somewhat heavier than atmospheric air. It is soluble in water, which at a temperature of 60° F. dissolves  $\frac{1}{36}$  of its volume of oxygen. Oxygen combines very readily with most of the elements, and forms oxids with all of them excepting fluorin. The act of combination is so energetic in many cases as to evolve light and heat, the phenomena of combustion. In other cases, as in the tarnishing or rusting of metals and the decay of animal or vegetable substances, oxidation takes place so slowly that, while the result is the same, the heat evolved at one time is not enough to produce luminous effects or even to be sensible. Free or uncombined oxygen is essential to all animal and vegetable life. Animal heat and muscular energy are results of a slow combustion produced in all parts of the system by oxygen carried in the blood from the lungs. In sunlight oxygen is exhaled by growing plants, but a certain quantity is assimilated and is essential to life. Oxygen is the most widely distributed and abundant element in nature; it constitutes about one fifth of the total volume of the atmosphere, which is a mechanical mixture of oxygen and nitrogen. Water contains about 89 percent. of it by weight, and it is found in most animal and vegetable products, acids, oxids, and salts. The rocks which make up most of the earth's crust contain between 40 and 50 percent. of oxygen. Under certain conditions oxygen may be made to pass into an allotropic or condensed form called *ozone*.

It was Lavoisier who gave to this curious kind of air or gas the name of *Oxygen*, by which it is now universally known; and it was he, too, who first showed, by the most conclusive experiments, what was really the composition of atmospheric air. His determination of the constitution of the air was made in the year 1777.

A Fossil Oyster, *Ostrea longirostris*.

*Ostreidae*, such as *Ostrea edulis*, the common species of Europe, and *O. virginica*, that of the Atlantic coast of the United States. The species are very numerous, and are found in all temperate and tropical countries, in salt and brackish water; there are also many fossil species. The shell is very irregular, both inequivalve and inequilateral, with one valve flattened and the other more concavo-convex, both rough outside and macreous inside. Each valve has one purplish eye or spot, showing where the single adductor muscle is attached, oysters being thus monomyarian. The gristly button-shaped body in the flesh is this ligament. The soft greenish substance corresponds to a liver. The fluted layers around a part of the body are the gills or breathing-organs. Oysters have sex, and are very prolific. They spawn in north temperate countries in May and June, during which period and for some time afterward they are not so good for food; whence the common saying that oysters are not eatable in those months which have no *r* in their names. The spawn or fry is called *spat* or *spat*. Oysters are now very extensively cultivated, the resulting stock being superior to the natural oyster. Starfishes and some carnivorous gastropods (see *borer*) are among the great obstacles to success with which oyster-culture has to contend. Oysters feed upon a great many different aquatic organisms of minute size. In confinement they eat corn meal greedily. See cuts under *ciborium*, *integripalliate*, and *Ostrea*.

*Oysters* in Ceu, *oysters* in graney, your helthe to renewe.

*Butler*, *Dyet's Dry Dinner* (1599). (*Hartlett*.)

The tongue of a Purple [a murex or some such shell] is about the length of a finger, so sharp and hard that he can open therewith the shell of an *oyster*.

2. One of many other bivalves of the same order, but of a different family. Thus, the pearl-oyster belongs to the *Ariculidae*.—3. [Slang.]—A **choking or stopping oyster**, a reply that leaves one nothing to say, as if choked with an oyster too large to swallow.

At an other season, to a felon lying to his rebuke that he was our deintie of his mouth and diete, he did with this reason give a *stopping oyster*.

 Checks and *choking oysters*.

Same as *cockscomb*, 3.—**Cove oyster**. (a) A name of oysters growing singly in or scattered over coves, creeks, bays, old planting-grounds, etc., too sparsely to be taken by the ordinary method of tonging, but captured singly in from four to eight feet of water with nippers. The density of ozone is one and one half times that of oxygen. It is produced when the electric spark is passed through air or oxygen, when a stick of phosphorus is allowed to oxidize slowly, and in various other ways. At a high temperature ozone is changed into ordinary oxygen, two volumes of the former yielding three volumes of the latter. Chemical tests show that ozone exists in the atmosphere to a minute extent, and in greater quantity in country districts than in towns, while in crowded thoroughfares it ceases to be recognizable. Ozone has a great power of destroying offensive odors, and is a powerful bleacher and an intense oxidizer.

The proportion of ozone in the air stands in a direct relation to the amount of atmospheric electricity present. *Roscoe and Schorlemmer*, Chemistry, I. 260.

When properly exposed, the degree of discoloration indicates the relative amount of ozone in the air. Ozone-papers are usually either red litmus-paper dipped in a dilute solution of potassium iodide, or paper saturated with a mixture of potassium iodide and starch. In the litmus-paper the ozone decomposes the potassium iodide and combines with the potassium, forming potash, by which the red litmus is rendered blue. In the iodized starch-papers, the ozone combines with the potassium, and the free iodine combines with the starch, forming a blue iodide of starch.

1. The sixteenth letter and twelfth consonant of the English alphabet, having a corresponding position in other alphabets. The scheme of parallel forms, as given in the case of the other letters (see especially *d*), is as follows:

ⲡ ⲡ ⲡ ⲡ  
Egyptian Hieroglyphic. Phœnician. Early Greek and Latin.

The usual Greek  $\pi$  was made by extending the originally short second perpendicular limb; the Latin (whence our *P*), by curving the same around to meet the perpendicular (see *k*). *P* in all these alphabets stands for the same unvarying sound; namely, for the surd labial mute corresponding to *b* as sonant, and *m* as nasal, made with closure of the lips, during the maintenance of which closure there is complete silence, its character being brought to light by explosion upon the following sound. The *p*-sound is in English much less common (below a third) than the *t*-sound, and slightly less common (about four fifths) than the *k*-sound. The character *p* has no varieties or irregularities of pronunciation in English save as it is silent at the beginning of a few Greek words, as *psalm*, *pneumatic*, *pteropod*, and, much more rarely, elsewhere, as in *receipt*, *account*. It enters into one important digraph, namely *ph*, found in numerous words of classical origin, and pronounced as *f* (but originally as written, or as an aspirated *p*, a *p* with an audible *h* after it, as in our compound *uphill*). (See *ph*.) According to the general law of correspondence, a *p* in the Germanic part of our language should represent an original *b*; but *b* appears to have been almost altogether wanting in the primitive language of our family; and hence our *p*, when not of classical origin, or borrowed from elsewhere, is the result of some irregular process.

2. As a medieval numeral, 400; with a dash over it ( $\overline{P}$ ), 400,000.—3. As a symbol: (a) In *chem.*, the symbol for phosphorus. (b) In *math.*, the Greek capital  $\Pi$  denotes a continued product.

Thus,  $\Pi_p (1 + p)$ , for which  $\Pi (1 + m)$  is also written, denotes the product  $(1 + m) m (m - 1) \dots 3 \cdot 2 \cdot 1$ . The small Greek letter  $\pi$  denotes the ratio of the circumference to the diameter, or  $3.14159265359 \dots$ . This notation was introduced by Euler. The other form of the Greek minuscule,  $\pi$ , denotes in astronomy the longitude of the perihelion.

2. A lineal measure of variable extent, representing the space naturally measured by the movement of the foot in walking. **(b)** Tubes of lead or other soft metal filled with some vegetable material, such as hemp or cotton. The ends of the tubes are either forced or soldered together.—**Oil-well packing**, a packing inserted between the pipe and the interior surface of the boring in an oil-well to keep surface-water, or water from the sides of the hole, from running into the well, and to prevent oil in some wells from being forced out around the pipe by a pressure of gas. The packing originally used was a leather bag filled with flaxseed, called a *seed bag*, made in the form of a ring. The flaxseed, swelling on being wetted, closed tightly the opening to be stopped. This packing swelled so tightly as to be very difficult to remove—a difficulty which led to the invention of many substitutes. One of these is the modern water packing, which consists of an annular leather packing, concave on the upper surface, surrounding the pipe, and held in position by a screw-joint. The weight of the superincumbent water presses this packing closely against the interior of the bore. Another form of oil-well packing, which stops efflux of oil under internal gas pressure, as well as influx of surface-water, is shown in the accompanying cut.

Oil-well Packing.

According to the position of the long in the first, second, third, or fourth place respectively, the foot assumes four forms, distinguished as *first pæon* (— — — —), *second pæon* (— — — —), *third pæon* (— — — —), and *fourth pæon* (— — — —). The pæon has a magnitude of five more or primary times (i. e., is pentasemic), its resolved form being the pentacach (— — — —). Three of these times belong to the thesis and two to the arsis, or vice versa (— — — —), or (— — — —), so that the pæon belongs to and is the type of the hemiolic or pæonic class of feet. Only the first pæon and the fourth pæon were in use in pæonic verse, the contracted form, known as the *Cretic*, being, however, more common; the second and third occurred in verses analyzed by the ancients as mixed Ionic, or epiconic. The *Cretic* (— — — —) was sometimes known as the *pæon diagios*, as distinguished from the *pæon epibatus* (— — — —), in which each short of the pentacach was doubled (i. e., represented by a long). The pæon received its name from its original use in compositions in honor of Apollo (see *pæan*). See *diagios*, *epibatus*. Also spelled, less correctly, *pæan*.

In the first *pæon*, an equivalent of the *cretic*, an arsis consisting of a long and short is followed by a thesis consisting of two shorts.

The Christian Church fixed itself first in the seats and centres of intelligence, in the towns and cities of the Roman Empire, and in them its first triumphs were won; while long after these had accepted the truth, heathen superstitions and idolatries lingered on in the obscure hamlets and villages of the country; so that *pagans* or villagers came to be applied to all the remaining votaries of the old and decaying superstitions, inasmuch as far the greater number of them were of this class. The first document in which the word appears in this its secondary sense is an edict of the Emperor Valentinian, of date A. D. 365. The word "heathen" acquired its meaning from exactly the same fact, namely, that at the introduction of Christianity into Germany the wild dwellers on the "heaths" longest resisted the truth.

chief if not the only exception was where a question was  
made as to a matter depending upon a record, in which  
case no jury was called, but the trial was by bare inspec-  
tion of the record. From these two classes of trials came  
the custom of designating matters which if litigated could

The ferns included in this genus differ from the living *Adiantum* in some details of fructification, and under the name of *Palæopteris* are included species previously referred by authors to the genera *Cyclopteris*, *Spheopteris*, *Neggerathia*, and others. This genus, as constituted by Schimper, is chiefly of Devonian age; but several species supposed to belong to it are reported from the Carboniferous. Same as *Archæopteris*. *Dawson*, 1871.

**Palæorhynchidæ** (pāl'ē-ō-rīng'ki-dē), *n. pl.* [NL., < *Palæorhynchus* + *-idæ*.] In Günther's system of classification, a family of acanthopterygian fishes, typified by the genus *Palæorhynchus*. They have a long compressed body, long vertical fins, a long beak (toothless or with very small teeth), the dorsal fin extending the whole length of the back, the anal reaching from the vent to the caudal, the caudal forked, and the ventrals thoracic in position and composed of several rays. The species are all extinct; they lived during the later Cretaceous and early Tertiary, and, as is supposed, in the deep sea.

**Palæorhynchus** (pāl'ē-ō-rīng'kūs), *n.* [NL., < Gr. *παύρος*, ancient, + *ῥιγχο*, snout, beak.] An extinct genus of fishes which were provided with an elongated beak resembling that of the swordfish, and which form the type of the family *Palæorhynchidæ*.

**Palæornis** (pāl'ē-ōr'nīs), *n.* [NL., < Gr. *παύρος*, ancient, + *ὄρνις*, a bird.] The typical genus of *Palæornithina*, founded by Vigors in 1825: so called because some bird of this kind was known to the ancients of Greece and Rome. One species was named by Linnaeus *P. alexandri*, on the supposition that it was that mentioned by Onesicritus, a historian of Alexander the Great. These birds are known as *ring-parrots*, from the characteristic collar around the neck. *P. torquatus* is the common ring-parrot of India, in parts of which country it abounds, sometimes in flocks of thousands. This appears to be the bird often figured as an attribute or accessory of some of the Hindu goddesses in sculpture and painting, like the owl of Minerva or the dove of Venus. *Palæornis* is the largest as well as the name-giving genus of its group, with upward of 20 species, inhabiting chiefly the oriental regions, but also Africa. The general color is green, the bill waxy-red in the male, the lores feathered, the tail long and emeate, the wings pointed, and the form rather lithe. The voice is very loud and harsh, but the birds may be taught to talk a little, and prove tractable in confinement. See cut under *ring parrot*.

**Palæornithidæ** (pāl'ē-ōr-nīth'i-dē), *n. pl.* [NL., < *Palæornis* (-ornith-) + *-idæ*.] The *Palæornithina* elevated to the rank of a family. In Garrod's arrangement, the usual scope of the group is extended to include the cockatoos, which are generally placed in a separate family, *Cacatuidæ*; in this case the family is divided into two subfamilies, *Palæornithina* and *Cacatuidæ*.

**Palæornithina** (pāl'ē-ōr-nī-thī'nē), *n. pl.* [NL., < *Palæornis* (-ornith-) + *-ina*.] A subfamily of *Psittacidae*, typified by the genus *Palæornis*, found in the Austroriparian region, India, and Africa, including Madagascar. They are technically distinguished by the presence of two carotids, and the absence of an ambiens. See *Palæornis*.

**palæornithine** (pāl'ē-ōr-nī-thīn), *a.* [*Palæornis* (-ornith-) + *-īn*.] Of or pertaining to the *Palæornithidæ*; possessing the characters of the *Palæornithidæ*: as, *palæornithine* genera.

The type species, *P. magnus*, was as large as a hedgehog.

Allen in 1878 upon remains from the insect-bearing shales of Florissant, Colorado. The species is named *P. bella*. It was little larger than a sparrow. Ellis, in which the introduction of new types is avoided by the distinctive use of all the available present forms (italic, roman, small capital, etc.) of the old types, some of them being turned and thus made to do double duty. Compare *Glossic* and *Nomic*.

**Palamedea** (pal'ā-mē'dē-ā), *n.* [NL. Horned Screamer (*Palamedea cornuta*).

long straight claws and hallux incumbent; the wing has a pair of stout spurs, metacarpal and phalangeal; and the head has a slender recurved horn, 3 or 6 inches long. Synonymous with *Anhimus*.

The skull is simply desmognathous, with recurved mandibular angle, conforming in

general to the lamellicornate type, though not in the shape of the rostral part; the tracheal structure is likewise anserine; the alimentary canal is very long, with sacculated ceca situated high up, and provided with special sphincters; the pterygosis is almost uniform, having only an auxiliary apteria; and the whole body, as well as the skeleton, is remarkably pneumatic. There are only 2 genera, with 3 species, *Palamedea corallia*, *Chamaechararia*, and *C. derbiana*. *Anahanda* is a synonym. Also *Palamedeidae*, as a subfamily.

**Palamite** (pal'ā-mīt), *n.* [*< Palam(us)* (see def.) + *-ite*.] One of the followers of Gregory Palamas, a monk of Mount Athos in the fourteenth century. Simeon, abbot of a monastery at Constantinople in the eleventh century, taught that by fasting, prayer, and contemplation, with concentration of thought on the navel, the heart and spirit would be seen within, luminous with a visible light. This light was believed to be uncreated and the same which was seen at Christ's transfiguration, and is known accordingly as the *Uncreated Light of Mount Tabor*. The doctrine was more carefully formulated and defended by Palamas, who taught that there exists a divine light, eternal and uncreated, which is not the substance or essence of deity, but God's activity or operation. The Palamites were favored by the emperor John Cantacuzene, and their doctrine was affirmed by a council at Constantinople in 1351. They were called by their opponents *Euchites* and *Masolians*. Also *Hesychast*, *Umbricantinus*.

The palanquin proper is a sort of box about 8 feet long, 4 feet wide, and

Palanquin.

as much in height, with wooden shutters made on the principle of the Venetian blind. It used to be a very common conveyance in India, especially among the European residents, but the introduction of railways and the improvement of the roads have caused it to be almost wholly abandoned by Europeans. In Japan the palanquin is called *norimono*, and is suspended from a pole or beam passing over the top. A similar conveyance called a *kiato* is extensively used in some parts of China; it is, however, furnished with long shafts before and behind instead of the pole, and is carried by mules. Compare *kago*.

*Palanquines* or little litters . . . are very commodious *Hakluyt's Voyages*, II. 221.

Also *palatal*.—*2.* Uttered by the aid of the palate, as certain sounds. See II., 2.—**Palatal glands, index.** Same as *palatine glands, index* (which see, under *palatine*).

**II. n. 1.** A palatine bone or palate-bone proper, one of a pair, right and left, of facial bones entering into the formation of the hard palate. They exhibit the utmost diversity of shape and relative size, but preserve constant position and relation in the bony framework of the upper jaw, where they are interposed between the supramaxillary bones in front and the pterygoid bones behind, and thus form an integral part of the preoral visceral arch. In their simplest form, the palatals are mere rods or plates extending horizontally from the pterygoids to the maxillaries. Their connection with the latter is closest, most frequently by fixed suture or ankylosis; with the former it is usually freer, often by movable articulation. There are many modifications of these bones in the lower vertebrates, and in the higher the tendency is to shortening, widening, heightening, and complete fixation, with some connections not acquired in lower animals. Such modifications reach a climax in man, where the palatals have a singular shape somewhat like the letter L, and very extensive articulations with no fewer than five other bones—the sphenoid, ethmoid, supramaxillary, maxillo-mandibular, vomer—and with each other. The bone here consists of a horizontal part, or palatal plate, which extends mesad and meets its fellow of the opposite side, thus forming the back part of the bony palate, and of a vertical plate which reaches into the orbit of the eye by a part called the *orbital process*. Each bone thus enters into the formation of the walls of three cavities, of the mouth, nose, and eye; it also assists to form three fossae, the zygomatic, sphenomaxillary, and pterygoid; it bounds part of the sphenomaxillary fissure, and contributes to closure of the orifice of the antrum of Highmore. The bone furnishes attachment in man to the zygoglossus muscle, the tensor palati, the superior constrictor of the pharynx, and both internal and external pterygoid muscles. Notwithstanding its complexity of figure and relations, it is a simple or single bone, developed in membrane from one center of ossification. See cuts under *Anura*, *craniofacial*, *Crotalus*, *desmognathus*, *dromaeognathus*, *Exilide*, *palatognathus*, *Phrynosoma*, *Python*, and *sphenoid*.

*2.* A sound usually produced by the upper surface of the tongue against a part of the palate further forward than that at which our *k* and *g* are made; but sometimes used of any sound made between the tongue and any part of the hard or soft palate. Thus, the German *ch* of *ich* is called palatal, and that of *ach* guttural; the Sanskrit has palatal sounds distinguished from gutturals; our *i* and *e* and *y* are called palatal, as also the compound *ch* and *j*. The term is a loose one, and requires definition as used by any authority.

**palatalization** (pal'ā-tal-i-zā'shōn), *n.* [*< palatalize* + *-ation*.] A making palatal; a conversion (especially of gutturals) into palatal sounds, as of *k* into *ch*, *g* into *j*, *s* into *sh*.

The palatalization of the guttural does not necessitate the coloring of the vowel. Amer. Jour. Philol., VII. 238.

**palatalize** (pal'ā-tal-iz), *v. t.*; pret. and pp. *palatalized*, ppr. *palatalizing*. [*< palatal* + *-ize*.] To make palatal; change from a guttural to a palatal pronunciation.

**palate** (pal'āt), *n.* [*< ME. palat*, *palet*, *< OF. palat*, *\*palet* (*F. palais*, arising from a confusion between *palais*, palace, and *\*palet*, *\*palé*, the vernacular OF. form) = It. *palato* (cf. Sp. *Pg. paladar*, *< L. as if \*palatāre*, *< L. palatum*, rarely *palatus*, the palate, the roof of the mouth.)

*1.* The roof of the mouth and floor of the nose; the parts, collectively considered, which separate the oral from the nasal cavity. Most of the palate has a bony basis, formed of the maxillary bones and palate-bones, or of special plates or processes of these bones, the extent of which represents the *bony* or *hard palate*. Behind this, and continuous therewith, in man and many other animals, is the *soft palate*, a musculomembranous fold or curtain hanging down between the back part of the buccal cavity and the upper part of the pharynx, technically called the *velum palati* or *veil of the palate*. The uvula hangs from the middle of the free edge of this velum, and its sides are continuous with the contracted walls of the passage, called the *pillars* or *arches of the palate*, and constituting the isthmus of the fauces. In osteology the term *palate* is of course restricted to the bony parts. In fishes the palate is that part of the roof of the mouth which corresponds to the palatal bones, behind the vomer and in front of the pharyngeals. See *palatal*, *n.*, 1, and cuts under *dromaeognathus*, *mouth*, *nasal*, and *tonsil*.

*2.* Taste; relish; from the idea that the palate is the organ of taste.

*4.* In bot., the projection of the lower lip of a personate corolla, more or less completely closing the throat, as in *Linaria* and *Antirrhinum*.—*5.* In entom., the epipharynx, a fleshy lobe beneath the labrum. See cut under *Hymenoptera*.—*Cleft palate*, a congenital defect of the palate such as to leave a longitudinal fissure in the roof of the mouth.

**palate** (pal'āt), *v. t.*; pret. and pp. *palated*, ppr. *palating*. [*< palatē*, *n.*] To perceive by the taste; taste.

The paleolithic epoch has been subdivided in various ways by different investigators in various regions. In France some have called deposits containing the rudest flint implements *Chellean*, from the locality St. Acheul near Amiens; other deposits with more finished work have been denominated *Moustérian* (from Moustier, on the Vézère); and those with objects of still higher grade of finish have received the names of *Solutérian* (from Solutré, Saône-et-Loire) and *Magdalenian* (from La Madeleine, on the Vézère). **Paleozoic**, **Palæozoic** (pā lē-ō-zō'ik), *a.* [= F. *paléozoïque*, < Gr. *παλαιος*, ancient, + *ζωή*, life.] In *geol.*, belonging to or constituting a geological formation characterized by the presence of ancient forms of life; applied to the oldest division of the geological series, beginning with the lowest stratified fossiliferous group, and extending upward to the base of the Triassic, or to the top of the Permian. The grand divisions of the Paleozoic are, proceeding upward or to groups later in age, the Silurian, Devonian, Carboniferous, and Permian. (See these words.) Of these the Permian is much the least important. The other divisions have been designated respectively as the "age of mollusks," the "age of fishes," and the "age of coal or of land-plants." The Paleozoic series may, from a paleontological point of view, be properly separated into two great divisions, a newer and an older. The former embraces the Silurian; the latter, the Devonian, Carboniferous, and Permian. The older Paleozoic is distinguished by the great predominance of graptolites, trilobites, and brachiopods, and by the absence of the fishes and amphibians, by the number and variety of the fishes and amphibians, by the disappearance of graptolites and trilobites, and by an extraordinarily developed flora, largely cryptogamic in character, from which a very considerable part of the coal of the globe has been formed. Rocks of Paleozoic age are spread over wide areas. They are especially important in the eastern and northeastern United States and in the Upper Mississippi valley, in which regions they usually form the surface rock, being covered only with detrital formations of the most recent age. Almost the whole of the bed-rock in New York and Pennsylvania is of Paleozoic age, and here the various groups of this series were studied out by the Geological Surveys of those States from 1834 on. To the labors of Sedgwick and Murchison in Wales and western England, carried on at about the same time with the beginnings of the New York and Pennsylvania Surveys, is due the larger share of the credit of disentangling the complicated structure of a region where the Paleozoic rocks are extensively developed, and it is there that the materials were obtained for the establishment by Murchison of the Silurian and Devonian systems, which, with the Carboniferous and Permian, form the Paleozoic epoch.

3. Chemical symbol, Pd; atomic weight, 106.5. One of the rare metals associated with platinum. It was separated from native platinum by Wollaston in 1803, and named after the planet *Pallas*, which had just before that time been discovered by Olbers. Palladium is dimorphous. It occurs in Brazil native, in minute octahedral crystals; and on the Harz it has been found in small hexagonal plates. It is, however, a decidedly rare substance, and the chief supply comes from the working over of the platinumiferous residues of various mints. It resembles platinum in appearance, but is harder; its specific gravity is 11.4. It fuses more readily than platinum or any other of the so-called platinum metals, melting, as is stated by some authorities, about as easily as wrought-iron. It is both ductile and malleable, and would be a very useful metal if it were not so scarce as to be expensive and irregularly attainable. The graduated surfaces of some astronomical instruments have been made of palladium, a use for which this metal is admirably adapted on account of its color and its unalterability in the air. Alloyed with silver, it has been employed by dentists as a substitute for gold.—*Palladium-gold*. See *porpizite*.

One of the planetoids revolving between the orbits of Mars and Jupiter: discovered (the second in the order of time) by Olbers, at Bremen, in 1802. On account of its minuteness, and the nebulous appearance by which it is surrounded, no certain conclusion can be arrived at respecting its magnitude. Its diameter has been estimated at 172 miles, and its period of revolution is 4.61 years. Its light undergoes considerable variation, and its motion in its orbit is greatly disturbed by the powerful attraction of Jupiter.

4. To reduce in violence; mitigate; lessen or abate; as, to *palliate* a disease. = *Syn.* *Palliate*, *Extenuate*, excuse, gloss over, apologize for. *Palliate* and *extenuate* come at essentially the same idea through different figures: *palliate* is to cover in part as with a cloak; *extenuate* is to thin away or draw out to fineness. They both refer to the effort to make an offense seem less by bringing forward considerations tending to excuse; they never mean the effort to exonerate or exculpate completely. They have had earlier differences of meaning, and *palliate* has a peculiar meaning of its own (see def. 3); *palliate* also would be likely to be used of the more serious offense; but otherwise the words are now essentially the same.

[= *F. pallium*, *OF. pallium*, *pallium* = *Sp. palio* = *It. pallio*, < *L. pallium*, a coverlet, mantle, cloak; cf. *palla*, a mantle, cloak; see *pall*.] **1.** In *Rom. antiq.*, a voluminous rectangular mantle for men, corresponding to the Greek himation (see *himation*), and considered at Rome, because worn by Greek savants, as the particular dress of philosophers; also, a toga or other outer garment; a curtain, etc., of rectangular shape.—**2.** *Eccles.*: (a) In the early church, a large mantle worn by Christian philosophers, ascetics, and monks. (b) A vestment worn by certain bishops, especially patriarchs and metropolitans. It seems to have come first into use in the Eastern Church, where it is known as the *omophorion*, and to have been worn by patriarchs, and given by them to metropolitans. Some authorities think that it was of primitive origin and at first worn by all bishops, while others hold that it was originally an imperial garment, bestowed by the emperor as a mark of distinction upon patriarchs and others, and afterward given to metropolitans and bishops generally. It has always been of wool, as indicating the pastoral office. It seems at first to have been a mantle rolled together and passed round the neck so as to fall both in front and at the back. It then became contracted in width and was worn nearly as it still is in the Greek Church as a wide wooden band fastened round the shoulders and descending nearly to the feet. In the Latin or Roman Catholic Church it gradually assumed a different shape, and is now a narrow band like a ring, passing round the shoulders, with two short vertical pieces, falling respectively down the breast and the back. It is ornamented with crosses, and has three golden pins by which it is attached with loops to the chasuble. The pallium was worn anciently in the Western Church by the Pope and by Gallican metropolitans. From the sixth cen-

tury it began to be given by the Pope to some metropolitans outside of his own diocese, in such of special favor or distinction—at first, according to some authorities, only with approval of the emperor. By the seventh or eighth century it came to be regarded as a sign of acknowledgment of papal supremacy. At present, in the Roman Catholic Church, a bishop elected or translated to a see of metropolitans or higher rank must beg the Pope for the pallium, and receives it after taking an oath of allegiance to the Pope. The Pope wears it whenever he officiates, bishops only on certain great feasts. Anglican archbishops no longer wear the pallium since the Reformation, but it forms part of the heraldic insignia of the archbishops of Canterbury, Armagh, and Dublin. Also called *pall*. (c) An altar-cloth; a frontal or pall.—**3.** In *emph.*, the mantle, mantle-flap, or mantle-skirt of a mollusk, an outgrowth of the dorsal body-wall. It is often wanting. See cuts under *Lamellibranchiata*, *Palaemon*, and *Tridacna*.

G. ball*; see *ball*), + *maglio*, < *L. malleus*, a mallet; see *mallet*.] **1.** A game, formerly played, in which a ball of boxwood was struck with a mallet or club, the object being to drive it through a raised ring of iron at the end of an alley. The player who accomplished this with fewest strokes, or within a number agreed on, was the winner.

To St. James's Park, where I saw the Duke of York playing *pelemelle*, the first time that ever I saw the sport. *Pepys, Diary, April 2, 1661.*

The game might develop into golf or *pell mell*. . . If the point played to was a hole in the ground, golf arose; if you played to a stone, tree, or rock, or through an iron hoop elevated on a post, *pell mell*, jeu de mail, Pila Malensis was the result. . . Lathier describes the attitude and "swing" at *pell mell* in words that apply equally well to golf. . . Generally speaking, the aim was to "loft" the ball, in fewer strokes than your adversary took, through an elevated iron ring.

mouse, corresponding to the planta of the pes or foot. In man the palm is fleshy, and presents two special eminences, the *thenar* (ball of the thumb) and, opposite to it, the *hypothenear*, mainly due to the bulk of the subjacent muscles. The habitual tendency of the fingers in grasping and holding throws the skin into numerous creases, several principal ones being quite constant in position. The character of these creases, in all their detail and variation in different individuals, is the chief basis of chiromony or palmistry. See phrases under *line*<sup>2</sup>.

G. palme* = *Icel. pálmur* = *Sw. palm* = *Dan. palme* = *F. palme* = *Sp. Pg. It. palma*, < *L. palma*, a palm-tree, palm-branch, the topmost branch, any branch, a palm-branch as a symbol of victory, also the fruit of the palm, a date, also the name of several other plants; so called from the resemblance of the

leaves of the palm-tree to the outspread hand; < *palmu*, the palm of the hand; see *palm*<sup>1</sup>. The Gr. name of the date-palm was *φαῖνός*; see *phoenix*.] 1. A tree or shrub of the order *Palmæ*. The palms form a natural plant-group of great interest, in appearance highly picturesque and often elegant, and in usefulness surpassed by no family except the grasses. The pulpy fruit of some species, most notably of the date, and the seed-kernel of others, prominently the coconut, are edible. Oil is yielded by the fruit-pulp of some (oil-palm) and by the seeds of others (coconut, *baobab*, etc.). The pith of the sago-palm is farinaceous, and the large terminal bud of the cabbage palm serves as a vegetable, as do the young seedlings of the palmyra. The sap of the wild date-tree and other species yields palm-sugar or jaggery; that of the coquito, palm-honey. The juice of various species becomes toddy or palm-wine, which in fermenting serves as yeast, and distilled affords a spirituous liquor. Aside from food and drink, the betel-nut, a kind of catechu, and a kind of dragon's blood are palm-products; a candle-wax exudes from *Ceroxylon*; vegetable ivory is the nut of the ivory-palm. Palm wood is useful for building (date-palm, palmyra, etc.), for fine work (porcupine-wood), for piles (palmetto), and for flexible articles (rattan). The leaves of many species serve for thatching (bussu-palm, royal palmetto, palmyra, etc.), for making hats, baskets, and fans, and in place of paper (palmetto, tatipot, etc.). The leafstalks of some (kittul, *piassava*) furnish an important fiber, as also does the husk of the coconut. There are many other uses. The coconut, date, and palmyra-palms lead in importance. The palm of the Bible is the date-palm. (For symbolic use, see def. 2.) As ornamental plants in temperate regions the palms are indispensable where sufficient hothouse room can be had.

2. A branch, properly a leaf, of the palm-tree, anciently borne or worn as a symbol of victory or triumph; hence, superiority; victory; triumph; honor; prize. The palm was adopted as an emblem of victory, it is said, because the tree is so elastic as, when pressed, to rise and recover its correct position. The Jews carried palm-branches on festal occasions, and the Roman Catholic and Greek churches have preserved this usage in celebrating the entry of Christ into Jerusalem. See *Palm Sunday*. See also def. 3.

3. One of several other plants, popularly so called as resembling in some way the palm, or, especially, as substituted for it in church usage. Among plants so designated are, in Great Britain, chiefly the great willow or goat-willow, *Salix caprea*, at the time when its catkins are out, and the common yew (the latter is universally so called in Ireland); in Europe also the olive, holly, box, and another willow; and in the northern United States the hemlock-spruce.

**Palmæ**<sup>2</sup> (pal'mē), *n. pl.* [*NL.* (Linnaeus, 1757), pl. of *L. palma*, a palm.] The palm family, an order of monocotyledonous plants of the series *Culgrineæ*, characterized by the one- to three-celled free ovary, solitary ovules, and small embryo immersed in a little hollow near the outside of the hard or oily albumen. About 1,100 species are known, classed in 129 genera 7 tribes, and 18 subtribes. They are mainly tropical, especially American, and are most abundant on coasts and islands; fewer in Asia and Australia; fewest in Africa; reaching lat. 44° N. in Europe, 36° in America, 34° in Asia. The species are usually local, excepting the coconut and four or five others. They are trees or shrubs, mostly unbranched, generally perennial, and continued only by a terminal and sometimes edible bud. Their large leaves are pinnately or radiately parallel-veined, undivided and plaited in the bud, divided slightly or completely on expansion. The flowers are small, regular, often rigid or fleshy, often dioecious, usually with six stamens, borne on a branching spadix, with several or many sheathing bract-like or woody spathe. The fruit is a berry or drupe or dry fruit, the outside commonly fibrous, within membranous, crustaceous, woolly, or stony. (Lyngbye, 1819)*, a dim. form, having reference to the jelly-like appearance; *< Gr. παλμός*, vibration, *< παύειν*, shake, vibrate.] A genus of fresh-water algae, typical of the *Palmellaceae*, having globose or oblong cells, with chlorophyll usually green, but sometimes changing to orange or reddish color. The cells are surrounded with a thick integument, which is generally soon confluent into a shapeless mass of jelly; multiplication is mostly by division. The forms included in this genus are probably not autotrophic, but represent arrested polymorphic forms which multiply rapidly by the process of cell-multiplication, without developing, for a protracted period, the true plant. The particular plants, however, to which they belong have never been determined. — **Palmella stage**, or **palmella condition**, a general phrase sometimes applied to certain of the lower algae which exhibit the peculiar gelatinous masses described above. In the *Schizosporites* this condition or stage has lately been called the *zoophora stage*. See *Zoophora*.

A pilgrim who had returned from the Holy Land, had fulfilled his vow, and had brought with him a palm-branch to be deposited on the altar of his parish church; hence, an itinerant monk who went from shrine to shrine, under a perpetual vow of poverty and celibacy. The distinction between *pilgrim* and *palmer* seems never to have been closely observed.

**palmerin** (pāl'mēr-in), *n.* [*< Palmerin* (see *def.*).] One of a line of romantic heroes of the age of chivalry, who took their names or their titles from Palmerin de Oliva, an illegitimate grandson of a Greek emperor of Constantinople. This Palmerin derived his name from the circumstance of his exposure in a wicker basket on a mountain-side among palms and olive-trees in Spain. He afterward became famous for his exploits in Germany, England, and the Orient. The exploits of the Palmerins, as celebrated in the famous Spanish romances called by their name, are evidently modeled after those of Amadis of Gaul. In literature the name is often applied as a term of distinction to any redoubtable champion of the age of chivalry.

That brave Rosicler  
That damned brood of ugly giants slew,  
And *Palmerin* Frasnarc overthrew.  
*Beau, and FL, Knight of Burning Pestle*, iii, 2.

The oldest ballads tell us nothing at all . . . of the *Palmerins*, nor of many other well-known and famous heroes of the shadow-land of chivalry.

*Ticknor, Span. Lit.*, I, 119.

**palmer-worm** (pām'ēr-wōrm), *n.* [*< palmer<sup>2</sup> + worm*.] 1. A caterpillar; especially, a hairy caterpillar injurious to vegetation, but what kind is unknown or undetermined. The name occurs three times in the Bible (Joel i, 4; ii, 25; Amos iv, 9) as the translation of the Hebrew *gizim*, rendered in the Septuagint *κατάν* and in the Vulgate *eruca*. Some have supposed it to be a destructive kind of locust, as *Pachytulus nigritarius*; but in Joel the name is expressly distinguished from "locust." The Hebrew name is referred to a root meaning "to cut off"; the Greek *κατάν* refers to the bending or looping of some caterpillars, apparently pointing to a looper or measuring-worm — that is, the larva of some geometrid moth; and the Latin *eruca* may have the same significance. The destructiveness of many of these geometrids would fully bear out the Biblical implication. See *oubt*.

There is another sort of these Caterpillars, who have no certain place of abode, nor yet cannot tell where to find their food, but, like unto superstitious Pilgrims, do wander and stray hither and thither, (and like Mice) consume and eat up that which is none of their own; and these have purchased a very apt name amongst vs Englishmen, to be called *Palmer-worms*, by reason of their wandering and roghish life (for they neuer stay in one place, but are euer wandering), although by reason of their roughnes and ragednes some call them *Beare-wormes*. They can by no means endure to be dyeted, and to feede vpon some certaine herbes and flowers, but boldly and disorderly creepe ouer all, and tast of all plants and trees indifferently, and live as they list. *Topsell, History of Serpents* (1608), p. 105.

That which the *palmerworm* hath left hath the locust eaten. *Joel* i, 4.

2. In the United States, the larva of the tineid moth *Ypsilophus pometella*, which in eastern parts of the country appears on the leaves of the apple in June, draws them together, and skeletonizes them.

**palmetto** (pal-met'ō), *n.* [Formerly *palmito*; *< Sp. palmito* (= *Pg. palmito* = *It. palmisto* = *F. palmiste*), dim. of *palma*, palm; see *palm<sup>2</sup>*.] Any one of several fan-leaved palms of different genera. The one most properly so called is *Sabal palmetto*, the cabbage-palmetto, a tree from 20 to 35 feet high, abounding on the southeast coast of the United States. It forms part of the device in the seal and flag of South Carolina, the Palmetto tree. Its wood is not attacked by the teredo and is very durable under water, and is therefore much used for piles and wharves. The fibrous leaves of this and the dwarf palmetto, *S. Adamsii*, are made into hats, baskets, and fans, and also furnish an upholstery material. The palmetto, or hemp-palm, of southern Europe and North Africa, is *Chamærops humilis*, a dwarf species, affording abundant food, consumed chiefly as "vegetable horsehair." The same names are given to the Chi-

Called in the West Indies *royal palmetto*.—**Silver-top palmetto**, the name in Florida of *Thrinax argentea*, a tree of the same range and size as the last, the leaves silvery-silky beneath. Its uses resemble those of the cabbage-palmetto. Also called *brickley* and *brittle-thatch*.—**Small palmetto**, a name of the palm-like genus *Carludovicia* of the natural order *Cycanthaceae*.

The labial palpi are two in number, rising either from the ligula or from the edge of the mentum; the maxillary palpi are placed one on the outer side of each maxilla. Besides these, certain *Coleoptera* have a second two-jointed palpitiform appendage on each maxilla, formed by a modification of the galea or external lobe. The palpi vary much in form and in the number of joints, which is never more than six; they are sometimes aborted or entirely absent, as in the *Hemiptera*. In the *Lepidoptera* this term is commonly restricted to the large labial palpi, the much smaller maxillary ones being distinguished as *palpuli*. The palpi are supposed by some to be organs of taste or touch. In the spiders the maxillary palpi are greatly developed, forming the pedipalps; these, in the scorpions, become chelate appendages, commonly called the front legs. Small palpi are also developed from the mandibles and maxillae of certain crustaceans. A splendid procession ascended to the shrine of the goddess on the Acropolis, and gymnastic games and musical competitions were held in the plain below. **pangeness** (pan-jen'e-sis), *n.* [NL., *< Gr. πᾶν (pān), all, + γένεσις, production*.] A provisional hypothesis advanced by Darwin to explain the phenomena of reproduction in organisms. It rests on the assumptions that the organic units (cells) of which an organism is composed differ from one another according to the function of the organ to which they belong; that they undergo multiplication by budding or proliferation, giving rise to minute gemmules, which are diffused to a greater or less extent throughout every part of each organism; that these gemmules possess the properties which the unit had when they were thrown off; and that when they are exposed to certain conditions they give rise to the same kind of cells from which they were derived. The name is also applied to the theory or doctrine that every organism has its origin in a simple cell called a *pangenetic cell*.

I venture to advance the hypothesis of *Pangeness*, which implies that every separate part of the whole organisation reproduces itself. So that ova, spermatozoa, and pollen-grains—the fertilized egg or seed, as well as buds—include and consist of a multitude of germs thrown off from each separate part or unit.

It consists of four perforated limbs or rules, *a, b, d, e*, of wood or metal, arranged in pairs, jointed together at the crossing, the two pairs being also

Pantograph.

*a, b, d, and e* are rules perforated with a series of holes placed at graduated distances for adjustment to different scales for enlargement or reduction of the picture to be transcribed; *a* and *b* are permanently but movably jointed at *f* to a traversing support; *d* and *e* are similarly jointed at *h* to a pencil-holder or point-holder; *ff* are thumb-screws which act as pivots for joining *a* and *d* and *b* and *e*. The rule *a* is pivoted by a support *i* which is fixed to the drawing table; *g* is a stylus attached to the end of the rule *b*. Lines traced by *g* will be also drawn by *h* on a larger or smaller scale corresponding to the adjustment.

jointed together at *c* and *h*. The perforations are made at uniform distances, in accordance with a scale of measurement. The pivoted joints by which the two pairs are connected are constant, while the joints between the intersecting limbs of each pair may be shifted by inserting the joint pins *ff* in different holes in each limb. By changing the pins the copy may be reproduced on any scale either larger or smaller than the original, or it may be kept of the same size, the proportion being indicated for convenience by figures on the limbs (not shown in the cut). In use, the end pivot *i* is fixed to the table, the pivot *c* sliding on the plane surface according to the impulse given to it. The pivot *a* carries a tracing-point which is passed over the original lines to be reproduced, and the pivot *h* carries a pencil or needle which traces the copy or pricks it in the paper. The pantograph is used for transferring patterns to calico-printing cylinders, in some processes of wood-carving, in making wooden type, etc. — **Polar pantograph**, a modification of the pantograph arranged for reproducing profiles of curved figures, as the tread of a car-wheel, the interior of a bell, or any other irregular form. It consists essentially of two arms supported in a light frame and united by means of a rack on each and a pinion common to both, so that the movement of one arm controls that of the other. When the point of the instrument is placed against the tread of a car-wheel, and is moved over it, the other arm reproduces a tracing that is an exact copy of the tread, showing such flattened places as may have resulted from wear, and such other irregularities as are present.

The *pantuns* are improvised poems, generally (though not necessarily) of four lines, in which the first and third and the second and fourth rhyme. They are mostly love poems; and their chief peculiarity is that the meaning intended to be conveyed is expressed in the second couplet, whereas the first contains a simile or distant allusion to the second, or often has, beyond the rhyme, no connexion with the second at all. The Malays are fond of reciting such rhymes "in alternate contest for several hours, the preceding *pantun* furnishing the catchword to that which follows, until one of the parties be silenced or vanquished."

The fibers most used for writing-papers are those of linen and cotton rags, and for printing-papers those of straw, wood, paper-cuttings or paper-waste, and selected grasses. These fibers are prepared by gridding, bleaching, beating, and boiling until they are reduced to a fluid pulp, in which state they readily mat or felt together when freed from the water in which they are suspended. More than 400 varieties of fibers usable for this purpose are known; all have curling filaments that readily interlace with one another. Paper was formerly made wholly by hand, pulp from the vat being dipped up in a mold, from which the water drains away, leaving a felted sheet, which is then pressed and dried. Some fine grades of writing, printing, and drawing-papers are still made in this way, but the larger part of the paper, for whatever purpose used, is now made by machinery. For some purposes, as newspaper-printing, the sheet is made in continuous webs of very great length, and is printed from the uncut roll. Paper is made in a great variety of qualities, ranging from heavy drawing-board to the lightest tissue-paper, and in every color and shade. It is cut for the trade by accurate machines in a number of sizes, the sheets varying somewhat according to fashion or special requirements. (See list of sizes given below.) Paper is also molded from the pulp into cartridge-cases, embossed sheets for wall-decoration, pails, boxes, and other vessels, boats, barrels, car-wheels, donies for observatories, bricks, building materials, etc., in all of which lightness is combined with strength. From the sheet it is transformed by various processes and operations into roofing material, carpets, bags, etc. The principal varieties of ordinary paper are—writing, and printing-papers, coarse papers for wrapping and other purposes, and blotting and filtering-papers; while some useful kinds are the result of manipulations subsequent to the paper-maker's work, as lithographic paper, tracing-paper, etc. The ordinary counts of paper are the quire of twenty-four sheets, the ream of twenty quires (of which two are inferior to the other eighteen), and the bundle of two reams.

A sheet of transfer-paper is laid upon the object; on this is laid the design executed on paper or other thin and yielding material, and the lines of the design are then passed over with a hard point, which causes the pigment of the transfer-paper to adhere, along the lines passed over, to the object under treatment. —Tub-sized paper, paper made by dipping each sheet in a tub that contains prepared animal sizing. —Turmeric-paper, paper dipped into a hot infusion of turmeric, strong enough to give the paper a pronounced yellow color, and dried; used as a test of alkalinity or acidity. —Vellum paper, a heavy, uniform paper, showing no grain, and having a very smooth and fine surface. It is important that the paper used shall be homogeneous and free from grain. Such negatives are convenient from their lightness and unbreakableness.

pean swallowtail, *P. machaon*, as the type species of the genus; Scudder (1872) decides that *P. antiope* is the type. By most entomologists the name is now restricted to swallow tailed butterflies having ample wings, triangular fore wings, hind wings concave next to the body and usually extended behind into a tail before the anal angle, and outer margin of hind wings dentate, with the teeth quite prominent near the tail. The genus thus defined is of world-wide distribution, with about 350 species. The common yellow and black butterfly of North America, *P. turanus*, is a good example. Another is the common swallow tailed butterfly of Europe, *P. machaon*, with long antennae, very short palpi, and the hind wings tailed. This species expands about three and one half inches, is yellow and black, with a red spot at the anal angle. Some of the papilios are giants, as *P. antiope* of Africa, expanding about eight inches. See *Equites*, 2, and also cut under *Papilionidae*.

3. [*i. e.*] Some or any butterfly; especially, a member of the genus *Papilio*.

See also cut under *corolla*.

**Papilionidae** (pā-pil'i-ō-nī-dē), *n. pl.* [NL. (Leach, 1819), < *Papilionus* + *-idae*.] A family of butterflies, typified by the genus *Papilio*, usually considered the highest of the diurnal *Lepidoptera*, or *Rhopalocera*. They have broad wings erect in repose, the hind wings concave along the abdominal border, slender antennae with the knob straight or scarcely curved, slender body, and six functional legs of which the first pair is of normal size and directed forward. The larvae are smooth or only moderately pilose, never spinose, thicker in front, tapering behind, with two retractile tentacles on the segment behind the head. The chrysalids are naked, angular, fastened to a button of silk, and hung by a silken loop a little above the middle of the body. The family is divided into 2 subfamilies, *Papilioninae* and *Pierinae*, to which some add *Parnassiinae*. (Other forms of the word are *Papilionus* (Balman, 1816); *Papilionida* (Leach, 1819); *Papilionidae* (Latreille, 1802); and *Papilionidi* (Goisshval, 1829).) See also cuts under *Papilio*.

See *engorge*. **Foliate papillae**, small folds of mucous membrane on the sides of the tongue, immediately in front of the anterior pillar of the palate. **Fungiform papillae**, papillae intermediate in size and number between the circumvallate and the conical papillae, scattered over the dorsum of the tongue, but more numerous along the sides and at the tip. They are few and small in many parts of the body endowed with comparatively little sensibility, but in some places, especially the palmar and plantar surfaces of the hands and feet, and about the nipple of the breast, they are very large and numerous, and set in special curved lines, thus throwing up the cuticle into the many little ridges observable at the tips of the fingers, for example. **parabola<sup>1</sup>** (pa-rab'ō-lā), *n.* Same as *parabole*.

Whenever by your similitude ye will seem to teach any moralitie or good lesson by speeches mystical and darke, or faine fette, vnder a sence metaphorical applying one natural thing to another, or one case to another, inferring by them a like consequence in other cases, the Greekes call it *Parabola*. *Pottenham, Arte of Eng. Poesie*, p. 205.

**parabola<sup>2</sup>** (pa-rab'ō-lā), *n.* [= F. parabole = Sp. parabola = Pg. It. parabola, < NL. parabola, a parabola, < Gr. παραβολή, a parabola (see def.), so called by Apollonius of Perga, lit. "superposition," < παραβάλλω, throw beside, compare; see parable<sup>1</sup>.] 1. A curve commonly defined as the intersection of a cone with a plane parallel with its side. The name is derived from the following property. Let the figure represent the cone. Let ABG be the triangle through the axis of the cone. Let DE be a line perpendicular to this triangle, cutting BG in H. Let the cone be cut by a plane through DE parallel to AG, so that the intersection with the cone will be the curve called the parabola. Let Z be the point where this curve cuts AB. Then the line ZH is called by Apollonius the diameter of the parabola, or the principal diameter, or the diameter from generation; it is now called the axis. From Z draw ZT at right angles to ZH and in the plane of ZH and AB, of such a length as to make ZT:ZA::BG<sup>2</sup>:AB AG. This line ZT is called the latus rectum; it is now also called the parameter. Now take any point whatever, as K, on the curve. From it draw KL parallel to DE, meeting the diameter in L. ZL is called the abscissa. If now, on ZL as a base, we erect a rectangle equal in area to the square on KL, the other side of this rectangle may be precisely superposed

Parabola, as formed from cone.

upon the latus rectum, ZT. This property constitutes the best practical definition of the parabola. If a similar construction were made in the case of the ellipse, the side of the rectangle would fall short of the latus rectum; in the case of the hyperbola, would surpass it. The modern scientific definition of the parabola is that it is that plane curve of the second order which is tangent to the line at infinity. The parabola is also frequently defined as the curve which is everywhere equally distant from a fixed point called its focus, and from a fixed line called its directrix. The normal to a parabola at every point on the curve bisects the angle between the line parallel to the axis and the line to the focus. See also *cut under conic*.

2. By extension, any algebraical curve, or branch of a curve, having the line at infinity as a real tangent. Such a curve runs off to infinity without approximating to an asymptote. If the branch has an asymptote at one end but not at the other, it is not commonly termed a parabola. —Bell-shaped, biquadratic parabola. See the adjectives. —Campaniform parabola, a cubic divergent parabola without node or cusp. —Cartesian parabola, a plane cubic curve having the line at infinity a tangent at its crunode. See *trident*. —Cubical or cubic parabola, a parabola of the third order—that is, such that every line in the plane meets it in three points, one at least real, though it may be at infinity; especially, the curve better described as the *central cubical parabola*, which has a cusp on the line at infinity, and the normal at its inflection passing through the cusp. There is also a non-plane curve so called. —Cuspidate parabola, a parabola having a cusp. —Divergent parabola, a plane curve having the line at infinity as an inflectional tangent. —Double parabola, a plane curve of the third class, having the line at infinity for a double tangent. —Helicoid parabola. See *helicoid*. —Neilian parabola, the semicubical parabola, which was rectified, before any other curve, by Wm. Neil in 1657. —Nodate parabola, a parabola having a crunode. —Oval parabola, a parabola having an oval. —Plane cubic parabola. See *cubic*. —Punctate parabola, a parabola having an acnode. —Semicubical parabola, the cuspidal cubical parabola, otherwise called the *Neilian parabola*.

the cut, the angle BCD, being the semidiameter of AB as seen from C, is the parallax of C as seen from B. In astronomy, parallax is due either to our daily motion round the center of the earth, or to our yearly motion round the sun. There is also an effect of parallax when we alternately shut one eye and open the other.

In *geom.*, of lines (according to Euclid in his definition of parallel straight lines), lying in the same plane but never meeting however far they may be produced in either direction; of planes, never meeting however far they may be produced; in modern geometry, intersecting at infinity. The definition of Euclid is the traditional one; but the modern definition has three logical advantages: first, it is not, like the Euclidean definition, a negative one; second, it makes one conception applicable equally to parallel lines and parallel planes; and third, it is a statement which, whether literally true or not, must be admitted in form for the sake of the important generalizations which result from it.

2. Having the same direction, tendency, or course.

4. In *music*: (a) Of two voice-parts, progressing so that the interval between them remains the same. Such progression is called *parallel motion*, and the intervals by which the two parts are separated are called *parallel intervals*. When the interval is a unison, an octave, or a perfect fifth the progression is regarded as faulty; such progressions are called *parallel unisons, octaves, or fifths*, or simply *parallels* or *consonances*. Parallel thirds and sixths are correct, and pleasing when not too long continued. Parallel seconds and sevenths are rare, and usually objectionable. (b) Of tonalities, same as *relative*.—5. (a) Defined by Euclid as "straight lines which are in the same plane and, being produced ever so far both ways, do not meet." (b) *Milit.*, same as *parallels*. See 11, 5. — **Parallel motion**. (a) A contrivance for converting reciprocating circular motion into rectilinear reciprocating motion by the use of link-work. The ordinary parallel motion, that of Watt, fulfils its function to a close degree of approximation, but not exactly. It is designed to cause the piston-rod in imparting motion to, and the pump rod in taking motion from, the oscillating beam of a steam-engine, to move respectively in very nearly right lines, and is sufficiently perfect for all practical purposes. It depends upon the principle that when the ends of two levers connected by a link oscillate on different centers in the same vertical plane, describing arcs convex toward each other, there is some point in the connecting-link that must move in nearly a right line. The position of this point depends upon the lengths of the levers and the relative positions of their fulcrums. A method for mathematically locating this point has been given by Rankine. In the diagram the ends of the equal levers *gh* and *ij* describe arcs convex toward each other; *a* is the connecting-link; *q* and *j* are the fulcrums. The piston-rod is connected at *b* to the link *c*, and when the levers are caused to oscillate, one end of the link *a* is drawn to the right, while the other is moved to the left, causing the point of connection, and also the pump-rod *f* and piston-rod *e*, to move in nearly right lines. The first exact parallel motion discovered, after immense labor by many mathematicians, was Peaucellier's cell. (See *cell*.) The simplest is the Kempe-Sylvester parallel motion. (b) In music. See *motion*. — **Parallel perspective, rod**, etc. See the nouns. — **Parallel roads**, benches or terraces on hill-slopes, indicating former levels at which the water stood in the valley beneath at a time when this was occupied by a lake, or a lake-like expansion of a river. The phrase *parallel roads* is chiefly used with reference to the so-called Parallel Roads of Glenroy in Scotland, in regard to which there has been much discussion among geologists. See *terrace*. — **Parallel rulers**, an instrument for plotting courses on a chart, or for drawing parallel lines for other purposes. It consists of two rulers connected by cross-bars of equal length, movable about joints, so that while the distance between the two rulers may be increased or diminished, their edges always remain parallel. — **Parallel sailing, sphere**, etc. See the nouns. — **Parallel sulcus**. See *parallel fissure*.

Also called *almucantars*.—**Parallels of declination**, small circles of the celestial sphere parallel to the equator.—**Theory of parallels**, the geometrical discussion of the number of lines which can be drawn through a given point parallel to a given line, with other kindred matters. The fifth postulate (in some modern editions the eleventh axiom) of Euclid reads, "And if a right line incident upon two right lines make the two interior angles on the same side less in sum than two right angles, then those two right lines will meet on the side on which the angles are less than two right angles if produced to infinity." This proposition being much more complicated than any other assumed by Euclid without proof, a great number of attempts were made by mathematicians to demonstrate it. Finally, it was conclusively shown, as Gauss expressed it, that we have no reason to believe that the celebrated postulate is more than approximately true. There are thus three possible systems of geometry, the Euclidean and two non-Euclidean systems, according as it is assumed that there can be drawn through any given point, parallel to any given line, only one line, two real lines, or two imaginary lines.—**Zodiacal parallel**, in *astron.*, the situation of two planets at the same distance from the equator.

Why rather, being entering into that presence where I shall wake continually and never sleep more, do I not interpret my continual waking here to be a *paraseve* and a preparation to that? *Donne*, Devotions, Works, III, 567.

Specifically—2. Friday, the day before the Hebrew sabbath: so named because on that day the Hebrews prepare what is necessary for the next day; also, what is thus prepared. The name is retained in the Roman Catholic missal as a term for Good Friday, and is sometimes improperly applied to Thursday of Holy Week, or Maundy Thursday.

It was the *paraseve*, which is the Sabbath eve. Mark xv. 42 (Rheims trans.).

The sacred towell and the holy cure  
Are ready by, to make the guests all pure;  
Let go, my Alma; yet, ere we receive,  
Fit, fit it is we have our *Paraseve*.  
Who to that sweet bread unprepared doth come,  
Better he starv'd than but to taste one crumme.

**parasecretion** (par'a-sē-kre'shon), *n.* [*< Gr. παρά*, beside, + E. *secretion*.] 1. In *pathol.*, the production of a secretion of abnormal quality.—2. The substance thus secreted.

Paraselenic.

number of ice-crystals floating perpendicularly or vertically: a mock moon. Two or more paraselenae are generally seen at the same time, together with additional arcs or bands variously arranged. Paraselenae are entirely analogous to parhelia. See *parheliom*.

**Parasita** (par-a-si'tä), *n. pl.* [NL., neut. pl., < L. *parasitus*, m., a parasite; see *parasitic*.] In *zool.*, parasites; parasitic animals: applied to several different groups whose members are characterized by their parasitism. (a) In *Crustacea*, low parasitic forms, as the siphonostomes and related crustaceans, often collectively called also *Epipiza*, and made a class or order of that name. Most of them are known as *fish-lice*. (b) In *entom.*, lice; in Latreille's system, a group of apterous insects, the third order of insects, corresponding to the *Anoplura* of Leach. Also *Parasitica*.

*Bulwer*, What will he do with it? viii 7. (*Darvies*.)

**parasite** (par'a-sit), *n.* [*< F. parasite* = Sp. *parásito* = Pg. *parasito*, *parasita* = It. *parassito* = G. Sw. Dan. *parasit*, < L. *parasitus*, m., *parasita*, f., < Gr. *παράσιτος*, one who eats at another's table, a guest, esp. in a bad sense, a parasite, cf. *παράσιτος*, eat with another, live at another's table, < *παρά*, beside, + *σιτος*, food.] 1. Originally, one who frequents the tables of the rich and earns his welcome by flattery; hence, a hanger-on; a fawning flatterer; a sycophant.

I will despair, and be at enmity  
With cozening hope; he is a flatterer,  
A parasite. *Shak.*, Rich. II., ii. 2. 70.

Outstrip thus by a parasite! a slave,  
Would run on errands, and make legs for crumbs.  
*E. Johnson*, Volpone, v. 4.

Specifically—2. (a) In *zool.*, an animal that lives in or on and at the expense of another animal called technically the *host*; also, by extension, an animal which lives on or with, but not at the expense of, its host: in the latter sense, more precisely designated *inquiline* or *commensal* (see these words). There is scarcely any animal that may not or does not serve as the host of parasites, and some parasites are themselves the hosts of other parasites. (See *hyperparasite*.) Parasites form no technical group of animals, since representatives of almost any class or order, from protozoans to vertebrates, may be parasitic. Most of the leading divisions of animals, however, include some members, whether genera, families, orders, or even classes, whose habit is extensively or exclusively parasitic. Thus, among protozoans, the *Greeniada* are parasites. Among worms, many families, some orders, or even classes, are entirely parasitic, furnishing the most formidable and fre-

quent parasites of man and domestic animals. Very many of the lower crustaceans are parasites, especially upon fishes, mollusks, etc., and upon one another; while some of the highest crustaceans are modified parasites, or commensals, as the little crabs that live in oyster-shells. Among arachnids, the whole class or order of acarids or mites is essentially parasitic, though including many forms which lead an independent life. Insects furnish many of the parasites, especially of terrestrial animals, as vertebrates, and some are parasites of other insects. One order of insects, the *Anoplura* or lice, is thoroughly parasitic, and other orders furnish parasitic families or genera. Insects and crustaceans both belong to the phylum *Arthropoda*, and it may be said that as a rule insects furnish the arthropod parasites of land-animals, and crustaceans those of water-animals, or terrestrial and aquatic "lice" respectively. Few mollusks are parasitic, but *Entoeca mirabilis*, a gastropod found in holothurians, is an example. Very few vertebrates are parasites, but hags (*Myxine*) bore into fishes, fishes of the genus *Flaccaster* crawl into the intestines of holothurians, and some other fishes exhibit a kind of parasitism. Parasites not constituting any natural division of animals, it follows that, as such, they are not naturally divisible into zoological groups. They are, however, conveniently called *ectoparasites* or *ectoparasites*, according as they live in or on their hosts, or *Endozoa* and *Epizoa*, upon the same grounds. According to the extent or degree of their parasitism, they are also known as *parasites proper* and *commensals* or *inquilines* (see above). Among the most remarkable parasites are the males of some species which have their own females as hosts, as among cripids. Such males are known as *complemental males*, one or more of which are carried about by the female in her vulva, they being of insignificant size and to all intents and purposes mere male parts of her. The above-mentioned parasites are exclusive of all those many animals which are parasitic upon plants, as gall-insects and the like; and also of those birds which are parasitic to the extent of laying their eggs in other birds' nests, requiring their progeny to be hatched and brought up by foster parents, as cuckoos and cowbirds. See cut under *Cecropis*, *Eutamias*, *Epizoa*, *Platyphallia*, and *Stylops*. (b) Particularly, an insect which lives either upon or within another insect during its earlier stages, eating and usually destroying its host. Such parasites belong mainly to the *Hymenoptera* and to the *Diptera*, but there are a few coleoptera and lepidoptera to which the name may be applied. See cut under *Antigaster*. (c) In *bot.*, a plant which grows upon another plant or upon an animal, and feeds upon its juices. See *parasitic*, and cut under *Cercospora*.

Fungi have long been divided into two main sections founded on their nutritive adaptation. Those which constitute the first category feed on living organisms, whether plants or animals, and are termed *parasites*.

*De Bary*, Fungi (trans.), p. 356.

3. In *teratol.* See *autobis*.—**Autecious parasite**, in *bot.*, an organism which goes through the whole course of its development on a single host.—**Autogenous parasite**, in *bot.*, same as *autecious parasite*.—**Facultative parasite**. See *facultative*.—**Heterocious parasite**, in *bot.*, same as *heterocious parasite*.—**Metecious parasite**, in *bot.*, an organism which passes through the different stages of its development on widely different hosts, as some of the *Crustacea*.—**Metogenous parasite**, in *bot.*, same as *metecious parasite*.—**Obligate parasite**, in *bot.*, an organism to which a parasitic life is indispensable for the full attainment of its development. = *Syn. 1. Parasite*, *Sycophant*. The object of the *sycophant* is to ingratiate himself with one who is wealthy or powerful, and his means are especially servility and flattery. The *parasite* gets a maintenance or a more comfortable maintenance by living upon one who is richer; there is no suggestion as to the means employed, but the word is contemptuous as implying a relation of degradation. The derivational idea of *sycophant* is now quite lost; the secondary use of *parasite* in connection with plant and animal life now affects the original sense of the relation of human beings.

**parasitic** (par-a-sit'ik), *a.* [= F. *parasitique* = Sp. Pg. *parasítico* = It. *parassitico*, < L. *parasiticus*, < Gr. *παράσιτος*, parasite, < *παράσιτος*, a parasite; see *parasite*.] 1. Of the nature of a parasite; fawning for bread or favors; meanly dependent; acting the sycophant; like a parasite in any way; of things, secondary; subordinated to or arising from another thing of the same kind.

Specifically—2. In *zool.* and *bot.*, living or growing as a parasite; pertaining to or characteristic of parasites. See cut under *Oenothera*.

Parasitic bee, in *entom.*, one of several genera of true bees which are parasites or inquilines in the nests of other bees. Thus, members of the genus *Epeolus* of which *E. meratus* is an example live in the nests of *Colletes*; of *Colletes*, in the cells of *Megachile*; of *Megachile*, in the cells of *Anthophora*; and of *Stelis*, with *Osmia*. There can hardly be a doubt that in reporting speech or thought, all languages at first made use of the direct method, putting the actual words of the speech or thought after the verb of saying or thinking, without a connecting word: in other words, the first construction in such sentences was that of *parataxis*. *Amer. Jour. Philol.*, 1, 221.

**paratonic** (par-ā-ton'ik), *a.* [*< Gr. παράτονος, stretched out beside or along, < παρᾶ, beside, stretch out beside or along, produce, < παρᾶ, beside, + τένειν, stretch.*] Arresting or retarding plant movement or growth: a term proposed by Sachs, in 1865, to characterize the variations in intensity of light which produce the movements of waking and sleeping (nyctotropism) in plants, in contradistinction to heliotropism. It is the increasing intensity of light in the morning which induces the waking of the leaves, and the decreasing intensity in the evening which induces the closing or nocturnal position of the leaves, whereas in the heliotropic curving of motile organs it is the constant influence of light which effects the turning. As employed by other vegetable physiologists, the word implies also the retarding influence of light upon growing organs, in distinction from the *photonic* or stimulating effect upon leaves. That is, in leaves exposed for a protracted period to darkness the growth is arrested, but they have the power of growth restored on exposure to light, whereas all growing organs grow more rapidly in darkness than in light, this effect of light in retarding growth being termed the *paratonic effect*.

The power of movement, whether spontaneous or *paratonic*, may be temporarily suspended by certain external conditions. *Bessan, Botany*, p. 198.

**paratonically** (par-ā-ton'ik-āl-i), *adv.* In a paratonic manner; so as to manifest a paratonic effect.

Pardon is granted under the great seal or by warrant under the sign manual, countersigned by one of the principal secretaries of state, or by act of Parliament. Offenders against the laws of the United States may be pardoned by the President, except in cases of impeachment. Bacon, *Beauty*.

To beg, crave, or ask one's pardon, to ask one's forgiveness; a phrase corresponding in use to *pardon me* (which see, under *pardon*, *v.*) = **Syn.** *Pardon*, *Absolution*, *Remission*, *Amnesty*. All these words represent a complete work with reference to the offense, so that it becomes as though it had not been committed. *Pardon* is the general word (see comparison under *pardon*, *v. t.*). *Absolution* is now strictly an ecclesiastical word, as defined. *Remission* is, by derivation, a letting go, a sending away; "remission of sins" is a frequent Biblical expression; outside of Biblical language, we speak chiefly of the *remission* of penalty: as, the *remission* of a fine or of part of a term of imprisonment. *Amnesty* is strictly a political word, as defined, covering a general pardon of persons, named or unnamed, who have become exposed to penalty by offenses against the state or the sovereign. We speak of *pardon* of the offense or the person; *absolution* of the person from the offense; *remission* of sin or of penalty for the person; *amnesty* to all concerned in the insurrection.

Such persons would be within the general pardoning power, and also the special provision for *pardon* and *amnesty* contained in this act.

The blackest sin is clear'd with *absolution*.

**pare**<sup>1</sup> (pär), *v. t.*: pret. and pp. *pared*, ppr. *par-

etc., *empire*, *imperial*, etc., *parade*, *parry*, etc.]  
1. To trim by cutting or shaving off thin slices  
or flakes from the surface or the extremities;  
as, to *pare* an apple; to *pare* a horse's hoof, or  
one's nails; to *pare* old or worn-out grass-land.

=**Syn.** 1. *Pare*, *Peel*, *Shave off*. To *pare* is to remove the  
surface only with a knife or similar instrument; to *peel* is  
to pull off the skin or rind. "That is *peeled* which is de-  
prived of a natural layer or integument spread over it."  
(*C. J. Smith, Synonyms Discriminated*, p. 603.) The figura-  
tive uses of these two words are limited. *Shave* or *shave  
off* still seems figurative when not implying the use of a  
razor, and is controlled in its meaning by that original

sense; hence it is always limited to dressing off the sur-  
face.

**pareira** (pa-rā'rī), *n.* [Braz.] A drug derived  
from several plants. The true *pareira* (fully written  
*pareira brava*) is the root of *Chondrodendron tomentosum*,  
formerly supposed to be afforded by *Cissampelos pareira*,  
which is hence called *spurious pareira brava*. The latter  
has a local medicinal use. There are several substitutes  
for *pareira brava*, some of them worthless. The genuine  
is regarded as a mild tonic, aperient, and diuretic, but its  
chief use at present is to relieve chronic diseases of the  
urinary passages. *Pareira-root* is the official drug, but  
*pareira-bark* has probably something of its virtue. See

front; it sometimes had long and flow-

was usually made of some silk fabric, to  
some extent impermeable to rain.

(a) The proper tissue or substance of any part  
or organ, as distinguished from the connective  
or other sustentacular tissue which it contains.  
(b) The undifferentiated body-substance or  
chyme-mass of the unicellular animal, as an  
infusorian; indistinguishable cell-substance;  
endoplasm. (c) The general substance of the  
interior of the parenchymatous worms.—2. In  
*bot.*, the fundamental cellular tissue of plants:  
contradistinguished from *prosenchyma*, or fibro-  
vascular tissue. It is the soft thin-walled tissue, with  
approximately isodiametric cells, which composes the soft  
pulp of leaves between the network of veins, the pulp of  
fruits, etc. In a dicotyledonous stem it forms the outer  
bark, the pith, and the medullary rays; in monocotyledons  
it is the common mass, of loose texture, through which the  
definite fibrovascular bundles are distributed. While the  
ordinary or typical shape of the cells is polyhedral or spher-  
oidal, there are numerous modifications, all of which for-  
merly received special designations, but only a few prin-  
cipal types are now distinguished by names. Spongy paren-  
chyma is tissue in which the cells are loosely aggregated  
and have large intercellular spaces. Elongated paren-  
chyma-cells are more compactly combined than short ones,  
and in the upper side of leaves have received the signifi-  
cant name of *palisade-cells*. Flattened parenchyma-cells  
are seen in the medullary rays of dicotyledons. Collen-  
chyma, sclerotic and suberous parenchyma, trichomes,  
etc., are further modifications. See *collenchyma*, *palisade-  
cell*, *sclerotic*, *suberous*, *trichome*, and *cuts under cellular*,  
*cystolith*, and *tissue*.

tion, the second order of *Entozoa*, or intestinal

but are solid or parenchymatous. They were di-  
vided into four families—*Acanthocephala*, "*Trematoda*"

the composition of the order nor its subdivision corre-  
sponds with natural groups.

It is regularly included by two upright curves facing each other (also called *parentheses*), or the variant form of them called *brackets*, but frequently by dashes, and even by commas. The quotation from Dryden given below contains a parenthesis.

The parentheses ( ), including the square form [ ] also called *crochets* and now usually *brackets*, were formerly (as in the first quotation under def. 1) used to separate a word or words typographically, where quotation marks are now used. In phonetic discussions (Ellis, Sweet, etc.) the curves are often used for a similar purpose, to indicate that the letters of the words so inclosed have a fixed phonetic value, according to a system previously explained. The curves are also used to inclose small marks and letters, and figures of reference, in order to make them more distinct to the eye.

The phenomenon, on account of its rough resemblance to the sun itself, is popularly called a *mock sun*. Two or more par-

helia are seen at the same time; and variously arranged white circles, arcs, and bands intersect the halo, or lie tangent to it at the same points. Halos are produced by the refraction of rays through suspended ice-crystals which tend to fall in one or more special positions, and parhelia are due to the excess of crystals so situated. When the sun is near the horizon and the ice-prisms in a vertical position largely preponderate, parhelia are formed on the halo both to the right and left of the sun, and at the same level. As the sun rises, the parhelia gradually separate outward from the halo. If there is an excess of hexagonal prisms with their axes horizontal, and if the axes of the prisms are perpendicular to the line joining the sun and the observer, parhelia will be produced which will be situated on the halo above and below the sun.

As the sun rises, the parhelia gradually separate outward from the halo. If there is an excess of hexagonal prisms with their axes horizontal, and if the axes of the prisms are perpendicular to the line joining the sun and the observer, parhelia will be produced which will be situated on the halo above and below the sun.

In the *early Christian ch.*, a district placed under the superintendence of a bishop; a diocese.

The Word *Parochia* or *parish*, antiently signified what we now call the Diocese of a Bishop.

*Bourne's Pop. Antiq.* (1777), p. 268.

(*b*) Now, also, a civil division of the country for purposes of local self-government, such as the legal care of the poor, education, the regulation of sanitary matters, etc.; it is in general coterminous with the ecclesiastical parish. At present there are in England and Wales about 13,000 ecclesiastical parishes, and about 15,000 civil parishes, of which not more than 10,000 coincide with the ecclesiastical districts bearing the same name. In Scotland in 1888 there were 934 civil parishes or parishes proper (*quoad omnia*) and 386 parishes *quoad sacra* (that is, parishes in respect of things ecclesiastical only). There are several other minor classes of parishes, as the land-tax and Burial Act parishes in England, and the burghal and extra-burghal parishes in Scotland.

In the Protestant Episcopal Church the original form of the parish is more or less clearly adhered to, each diocese being as a rule divided into geographical parishes, and no new parish being formed or church established in cities without the consent of the three nearest parishes or congregations. (*d*) An ecclesiastical society, not bounded by territorial limits, nor confined in its personnel to communicants, but composed of all those who choose to unite in maintaining Christian work and worship in a particular local church: used in this sense chiefly in New England.

A park is an enclosed chase extending only over a man's own grounds. Specifically—3. [*cap.*] The supreme legislative body of the United Kingdom of Great Britain and Ireland, consisting of the three estates of the realm, namely the lords spiritual, the lords temporal, and the commons; the general council of the nation, constituting the legislature, summoned by the sovereign's authority to consult on the affairs of the nation and to enact and repeal laws. Primarily, the sovereign may be considered as a constituent element of Parliament; but the word as generally used has exclusive reference to the three estates above named, ranged in two distinct branches, the House of Lords and the House of Commons. The House of Lords includes the lords spiritual and lords temporal. (See *House of Lords*, under *lord*.) The House of Commons consists of 670 members; viz. for England and Wales, 253 representatives of county constituencies (counties or divisions of counties), 237 of boroughs, and 5 of universities; for Scotland, 39 representatives of counties, 31 of boroughs, and 2 of universities; for Ireland, 85 representatives of counties, 16 of boroughs, and 2 of a university. The authority of Parliament extends over the United Kingdom and all its colonies and foreign possessions. The duration of a Parliament was fixed by the Septennial Act of 1716 at seven years, but it seldom even approaches its limit. Sessions are held annually, usually from about the middle of February to the end of August, and are closed by prorogation.

Government is administered by the ministry (see *ministry and cabinet*), which is sustained by a majority in the House of Commons. Should the ministry be outvoted in the House on a question of vital importance, it either resigns office or dissolves Parliament and appeals to the country. The precursors of the Parliament were the Witenagemot in the Anglo-Saxon period and the National Council in the Norman and Angevin periods. The composition and powers of Parliament were developed in the thirteenth and fourteenth centuries; the right of representation from shires and towns dates from 1295, and the separation of the two houses dates from the middle of the fourteenth century. Parliamentary government was in large measure suspended from 1461 to the middle of the reign of Henry VIII. Prolonged struggles between the Parliament and the crown took place under James I. and Charles I., which led to the Civil War and the Commonwealth. The Triennial Act of 1694 (modified by the Septennial Act of 1716) fixed the life of Parliament at three years, and government by party dates from the same period. The right of election to Parliament has been greatly modified by the Reform Acts of 1832, 1867, and 1884, and the Redistribution Act of 1885.

I find that you have made choice of me to be one of your Burgesses for this now approaching *Parliament*. *Howell, Letters*, I. v. 4.

4. [*cap.*] One of similar legislative bodies constituting the legislatures of the Dominion of Canada, New South Wales, Tasmania, Victoria, and other self-governing colonies of the British empire. The Parliament of the Dominion of Canada, established by royal proclamation in 1867, consists of two houses—a Senate, or upper house, whose members, so in number, are nominated for life by the governor-general, and a House of Commons, whose members are elected for

five years by the people of the different provinces, there being one representative for every 20,000 of the population. In the other colonies the two houses are usually styled the *Legislative Council* and the *Legislative Assembly*. The members of the latter body are elected; the members of the former body may be elected, as in Tasmania, or nominated by the crown, as in New South Wales.

See the quotation.

In later times, the phrase is more commonly used of either house, or both houses, acting in the exercise of judicial or quasi-judicial functions, such as the inquest by the Commons and the trial by the Lords of an impeachment, or the action of either house, or both successively, on a bill of attainder, a question of contempt, the removal and punishment of public officers, etc., as distinguished from functions of legislation and functions as council of the king.

more specific names. When used in a stricter sense, it usually refers to Old World birds of moderate or rather large size, of stout build with strong beak, fleshy tongue, and short square tail, as in the restricted genus *Psittacus*, of which the African *P. erythacus*, of a gray color with a bright-red tail, is a characteristic example and one of the commonest of cage-birds. The natural cries of parrots are, as a rule, extremely loud and harsh; but many of the fleshy-tongued species can be taught to articulate words and even sentences in a perfectly intelligible manner. Most parrots are expert climbers, and in scrambling about use the bill as well as the feet, the upper mandible being peculiarly movable. The tongue in some species is also used as an organ of touch, almost of prehension, objects being often held and handled between the tip of the tongue and the hook of the beak. These birds are mostly vegetarian, feeding upon seeds and especially soft fruits, but some are carnivorous. Their temper is uncertain, though several kinds exhibit the most affectionate and gentle disposition, at least toward one another. In size and shape parrots differ greatly, more than is usual among the representatives of any one family of birds: some of the smallest species are no larger than sparrows, as those of the genus *Nesiterna*, while the great macaws attain a length of about three feet. Their coloration is equally diversified: some are black or gray; some are snowy-white; green is the most characteristic color; yellow, red, and blue, often of the most brilliant tone, are very common; and many parrots are variegated with all these colors. The sexes are usually colored alike. Gaudiness of coloration reaches its extreme in the macaws, while the most beautiful and dainty tinting is common among the lories, and plain or somber shades are exceptional throughout the order. Of parrots of all kinds there are about 350 species, classed in from 25 to 100 genera according to the views of different ornithologists. They abound in all tropical countries, but seldom extend into temperate countries, except Australia and New Zealand. In round numbers, the geographical distribution of parrots is as follows: America is richest in species, having 150, only one of which occurs in the United States, though two or three others come nearly or quite to the Mexican border; the Moluccas and Papuan Islands have 80 species, Australia 60, and Polynesia 30; 25 are African; and 20 are peculiar to Asia. See also cuts under *cuckatoo*, *Conurus*, *corolla*, *Euphonia*, *macaw*, *Metopidius*, and *parakeet*.

Parthenogenesis characterizes the reproduction of many insects, as aphids or plant-lice.

Agamogenesis is of frequent occurrence among insects, and occurs under two extreme forms: in the one the parent is a perfect female, while the gametes have all the morphological characters of eggs, and to this the term *parthenogenesis* ought to be restricted.

There are but two simple participles in English, usually called the *present* and the *past or passive*: as, *loving, loved; singing, sung*; in some languages there are more, as for example in Greek. Participles are much used in many languages, especially in English, in forming verb-phrases by combination with auxiliaries: thus, I am *giving*, I have *given*, it is *given*, etc.

The same power has of late been sometimes extended to personal property, but not usually under the name of *partition*, nor is the name used for the ordinary distribution or division of an estate by executors, etc.

Specifically — 2. In *law*, the relation subsisting between persons who combine their services, property, and credit for the purpose of conducting business for their joint benefit. It involves usually a reciprocal agency and a community of profits and of losses, and often a community of interest in the capital. Since one in such a relation may make himself liable as a partner to pay debts, and yet fail to secure the right to share assets, the test of what constitutes a partnership according as merely the relation of the parties to one another is considered, or their relation to third persons dealing with the firm. For the purpose of liability to third persons, a right to share in the profits as profits, as distinguished from receiving a compensation in proportion to profits, has been deemed the general test; but it is subject to exceptions and qualifications, and in England and some other jurisdictions the test is whether the relation was such that the one sought to be held liable had constituted the other his agent to contract such obligation.

3. The contract creating the relation of partners. — 4. A rule in arithmetic. See *partnership*.

4. — **General partnership**, a partnership in which the relation is not qualified as *limited* or *special*, and in which, therefore, all the members are jointly liable for all the debts. — **Limited partnership**, or **special partnership**, a partnership in which the special partner contributes to the common stock a specific sum in cash, and is liable for the debts of the partnership only to the amount of his investment. This immunity is secured by compliance with the statutes creating it, which usually provide that the special partner shall take no part in the conduct of the business. — **Mining partnership**, a partnership which exists when two or more persons, who own or acquire a mining-claim for the purpose of working it and extracting the mineral therefrom, actually engage in working the same: the chief peculiarity of the relation in this case is in the implied powers of the partners, and the fact that the transfer of the share of a partner to a stranger brings in the latter without dissolving the partnership. — **Universal partnership**, a form of association existing in Louisiana, in which all the partners agree to put in common all the wealth they have and may acquire. Exception, however, is now made of wealth acquired by gift, succession, or legacy after the partnership had been constituted.

**part-owner** (pär't'ô nér), *n.* In *law*, a joint owner or tenant in common, who has an independent, although an undivided, interest in property with another or others.

Pg. *perdriz* = It. *perdrice*, *perdriz*, < L. *perdris*, < Gr. *πιδρίς*, a partridge.] 1. A gallinaceous or rascorial bird of the family *Tetraonidae* and of one or

another of the subfamilies *Perdiciinae*, *Caccabinae*, and *Ortyginae*, of small size as compared with grouse (*Tetraoninae*), with four toes, scaly shanks seldom spurred, fairly well-developed tail, and naked nostrils. (a) The birds more particularly designated partridges are the European species of the genera *Perdix* and *Caccabis*. The best-known of these is the common gray partridge, *Perdix cinerea*, the only bird of

Common Gray Partridge (*Perdix cinerea*).

the kind that is common in Great Britain, and hence the one specifically called a *partridge* in English. It extends through Europe, and in Asia is replaced by closely related forms, as *P. barbara* and *P. hodgsonii*. Other Asiatic birds which have *partridge* as at least the book-name are species of *Oreopertis*, *Amurperdix*, *Arborophila*, *Bambusicola*, etc. Those of the last named genus are known as *bamboo partridges*. (b) In Europe other birds properly called partridges are species of *Caccabis*. The red-legged, French, or Guernsey partridge is *Caccabis rufa*; the Greek partridge is *C. graeca*; the rock-partridge is *C. saxatilis* and *C. petrosa*. Related to these in Asia and Africa are other species of *Caccabis*. Snow-partridges belong to the genus *Lerwa* or *Tetraopertis*, as *L. or T. nivalis*, and to *Tetraonallus*. Of the latter genus are the chukotka (*T. caspius*), the Himalayan partridge (*T. himalayensis*), and other species. The hill-partridges are a dozen or more species of *Arborophila*, found in India and countries further east, and several of *Gallopertis*. (See cut under *Gallopertis*.) The very numerous species of francolins are often brought under *Perdiciinae*, and some of them are called *black partridges*. They are mostly African. (See cut under *francolin*.) (c) All the partridge-like birds of America are entirely different from any of the foregoing, and constitute a separate subfamily called *Columbae*, *Oreopertis*, or *Oreopertinae*; these are in different parts of the United States (as explained under *phasianus*) known as *partridges* or *quails* (quail being properly the name of the Old World birds of the genus *Coturnix*). The common partridge or quail of the United States is the Virginian bobwhite, *Coturnix or Oryzopsis virginiana*, and it is the only one that is extensively dispersed in the country. But in the southwestern states and Territories are found numerous other partridges or quails, of the genera *Oreopertis*, *Lophortyx*, *Callipepla*, and *Centurus*; while ranging through Mexico and Central America and well into South America are yet others, belonging to the genera *Euphonia*, *Dendrocygna*, and *Oreopertis*. See cuts under *Coturnix*, *Callipepla*, *Centurus*, *holotrichus*, *Lerwa*, *Oreopertis*, *Oreopertis*, and *quail*. See also *grouse*.

By a misapplication of the name (by English sportsmen and others in South America), species of the family *Tinamidae*, as *Nothura maculosa*, the common partridge of the pampas of the Argentine Republic, and *Rhyecholus capensis*, the great or large partridge. — 3. In Australia, by misapplication, species of the family *Fringillidae*. — 4. In New England, by misapplication, the ruffed grouse. — 5. In *ornithology*, a large bombard formerly used in sieges and defensive works. *Froissart*. Compare *perdrone*.

sentative example of the *Oscines* or normal *Passeres*. The name lapsed, or was used with little discrimination, for a century, but is now in nearly universal use for that genus of finches which contains the common European or so-called English sparrow (*P. domesticus*), the European tree-sparrow (*P. montanus*), and several other closely related species. The two species named are both naturalized in the United States. See *sparrow* and *house-sparrow*.

(Bonaparte, 1838), < L. *passerculus*, a little sparrow, dim. of *passer*, a sparrow: see *Passer*.] A genus of American fringilline birds, embracing many of the commonest sparrows of the United States, of fully streaked coloration, with yellow on the bend of the wings, slender bill, short and narrow unmarked tail, and pointed wings with elongated inner secondaries. The common savanna-sparrow is *P. savanna*, and there are several others. They are ground-sparrows, and especially abound in low moist localities.

**Passerella** (pas-e-rel'ā), *n.* [NL. (Swainson, 1837), dim. of L. *passer*, a sparrow: see *Passer*.] A genus of large handsome fox-colored fringilline birds of North America, having enlarged feet; the fox-sparrows. *P. iliaca* abounds in shrubbery in most parts of eastern North America, and several other species or varieties are found in the west. See *fox-sparrow*.

**Passerellinae** (pas-e-rel'i-nē), *n. pl.* [NL. (S. P. Baird, 1838), < *Passerella* + *-inae*.] A subfamily of *Fringillidae*, named from the genus *Passerella*, having no definable characters.

**Passeres** (pas'e-réz), *n. pl.* [NL., pl. of L. *passer*, sparrow: see *Passer*.] An order of the

class *Acres*, typified by the genus *Passer*, comprehending more than half of all birds. It has about the taxonomic or classificatory value of groups called families in departments of zoology other than ornithology. It corresponds exactly to *Passeres* in some of the uses of this word, and exactly to the European *Passerinae* as intended by Blyth, also to the *Agelionanthia* of Huxley. It consists of the *Oscines* (Müller) and *Columbiformes* of Cabanis. With some exceptions, these birds (numbering upward of 5,000 species) have the following characters. They are monallogonous, having no ambis muscles nor accessory femorotendons. The femorotendons and semitendinosus muscles are present, as is usually also the accessory semitendinosus. The flexor longus hallucis, the muscle which bends the hind toe, is separated from the flexor longus digitorum, which bends the other toes collectively; and the hind toe is inserted low down, or is perfectly incumbent. The result of this is that the feet are perfectly fitted for grasping slender supports, and the birds are thus typically insectivorous. Furthermore, the toes are at ways 4, 3 in front and 1 behind (except in *Chlorornis*); none are versatile from their normal position, and the ratio of their phalanges is always 2, 3, 4, 5, counting from the first to the fourth digit. As to the means of flight, of which no *Passeres* are deprived, the sternum has with few exceptions a particular conformation, being notched on each side behind, manipulated, and provided with prominent costal processes; the tensor patagii brevis has a special mode of insertion; the primaries are either 10 or 9 in number, the secondaries are more than 6, and the greater coverts are not more than half as long as the secondaries. The tail has 12 rectrices (with few exceptions). The palate is agnathognathous, the covering of the bill is hard, with a cere or other soft membrane, and the nostrils do not openly communicate; the oil-sland is indurated; the cerea are 2 in number; and the carotid is single and sinistral. *Passeres* are altricial and psilopodae, the young being born helpless and naked. In most birds of this order the lower larynx, or syrinx, is highly developed as a musical organ, and according to this character *Passeres* are divisible into 2 primary groups—*Oscines* or *Aeropygidi*, and *Columbiformes* or *Mesomyodi*. The division of *Passeres*, however, has severely exercised alike the erudition and the ingenuity of the systematists, and no proposed method is fully accepted. The prime division by Garrod and Forbes, into *Eleutherodactyliti* and *Desmodactyliti*, is superfluous, since those alleged *Passeres* which are desmodactylitons are not *Passeres*. Elimination of these obstructive terms leaves the prime division as before, into *Aeropygidi* and *Mesomyodi*. In 1874 Wallace divided *Passeres* upon external characters into 4 series: (1) *turdoid*, with 21 families; (2) *tanagroid*, with 10 families; (3) *sturnoid*, with 4 families; (4) *formicarioid*, with 10 families; 45 in all—an arrangement requiring some modification upon anatomical grounds. The mesomyodian *Passeres* are either (1) heteromorphous, as the families *Columbidae* and *Pipridae*, or they are (2) homomorphous. The latter are either (1) haplophthonous, as the *Tyrannidae*, *Pittidae*, *Phylloscopidae*, and *Vireonidae*, or they are (2) tracheophthonous, as the *Furnariidae*, *Pteropodidae*, *Dendrocapitidae*, and *Formicariidae*. With few exceptions, mesomyodian *Passeres* are American, and nearly all of these (all but a few *Tyrannidae*) are Central and South American. As to the aeropyodian *Passeres*, they are either abnormal or normal. The abnormal *Passeres* are only two Australian families, *Menuridae* and *Atrichidae*, together called *Pseudoscines*. The rest are *Oscines* proper, some 4,700 species in all, so closely related that they scarcely represent a group of higher rank than the average 'family' recognized by ornithologists. They are three of Wallace's four series (*turdoid*, *tanagroid*, and *sturnoid*), and are separated by Sundevall into *Cichlomorphae*, *Conirostres*, *Columbiformes*, *Certhiomorphae*, *Cinnyriomorphae*, and *Chelidonomorphae*. Selater has six similar divisions, though in different order and under other names: *Dendroscopidae*, *Conirostres*, *Curvirostres*, *Tenuirostres*, *Conirostres*, and *Cultrirostres*. These groups may be thus explained or illustrated: (1) *Cichlomorphae* or *Dendroscopidae*, thrushes, warblers, flycatchers, shrikes, etc.; (2) *Columbiformes* or *Cultrirostres*, crows, jays, tits, etc.; (3) *Conirostres*, finches, buntings, sparrows, tanagers, etc.; (4) *Cinnyriomorphae* or *Tenuirostres*, honey-suckers; (5) *Certhiomorphae* or *Curvirostres*, creepers; (6) *Chelidonomorphae* or *Laticrostridae*, swallows. All these birds agree in being laminiplanar; and among them or near them must be found or made a place for the larks, *Alaudidae*, which are scintilliplanar, and which, when not placed with *Conirostres*, form a seventh superfamily known as *Corydromorphae*.

**passeriform** (pas'e-ri-form), *a.* [*L. passeriformis*, < *L. passer*, sparrow, + *forma*, form.] Sparrow-like in form or structure; pertaining to oscine *Passeres* or *Passeriformes*, or having their characters; passerine in a strict sense.

**Passeriformes** (pas'e-ri-for'mōz), *n. pl.* [*NL.*: see *passeriform*.] In Forbes's classification, an order of anomalogonous birds composed of *Turdiformes*, *Fringilliformes*, and *Sturniformes*, or the *turdoid*, *tanagroid*, and *sturnoid* *Passeres* of Wallace, and thus equivalent to oscine *Passeres*, or *Oscines*.

**Passerina** (pas'e-rī-nā), *n.* [*NL.*, fem. of *L. passerinus*, of or for a sparrow; see *passerine*.] 1. A beautiful genus of American *Fringillidae*: the painted finches. The plumage is of bright or variegated colors, or both, as in the indigo-bird, *P. cyanea*, which is rich blue, the lazuli-finch, *P. amoena*, which is blue, white, and brown, and the painted finch, or nonpareil, *P. ciris*, which is blue, red, and yellow. Vieillot, 1816. Also *Cyanospiza*. See cut in next column, and cut under *indigo-bird*.

2. A genus of heath-like shrubs, of the apetalous order *Thymelaeaceae* and the tribe *Euthymelaeae*, known by its four-lobed unappendaged urn-shaped calyx, eight exerted stamens, and globose stigma. There are 4 species, all South African, sometimes cultivated for their flowers. They bear little

decussate opposite leaves, and flowers in spikes with broad bracts. *Linnaeus*, 1737.

**Passerina** (pas'e-rī-nā), *n. pl.* [*NL.*, pl. of *Passerina*.] 1. In Cuvier's system of classification, the second order of birds, approximately equivalent to the *Passeres* or *perchers*; primarily divided into two groups, the ordinary *Passerina* and the *Syndactyli*, and, secondarily, the former into four groups, *Dentirostres*, *Fissirostres*, *Conirostres*, and *Tenuirostres*. As thus constituted, it was a thoroughly unnatural group, subdivided in an equally artificial manner. But removing from it certain heterogeneous elements, as *Cypselus*, *Caprimulgus*, *Podiceps*, *Colinus*, *Coracias*, *Pipua*, *Merops*, *Trochilus*, etc. (as was done by Blyth, Cuvier's editor in 1849), it represents the *Passeres* of modern naturalists.

2. In Nitzsch's classification, the expurgated *Passerina* of Cuvier, or *Passeres* proper.

**passerine** (pas'e-rī-nē), *a.* and *n.* [*L. passerinus*, of a sparrow, < *passer*, sparrow; see *Passer*.] 1. *a.* Resembling or related to a sparrow; of or pertaining to the *Passerina*, in any sense, or the *Passeres*; passeriform.—2. *n.* About as large as a sparrow; as, the *passerine* parrot, *Psittacula passerina*; the *passerine* ground-dove, *Chamaepelia passerina*; the *passerine* owl, *Glauclaudia passerina*.

**passion-music** (pash'ôn-mû zik), *n.* The music of a *passion-play*; a form of cantata or oratorio treating of the sufferings and death of Christ. The idea of such works appeared in very early Christian times, having a strictly liturgical origin. Its later development has tended somewhat toward concert-music. The personages usually introduced are the Evangelist or Narrator, the Saviour, the Disciples, the People, etc.; allegorical or idealized characters also occur. Recitatives, solos, duets, choruses, and even instrumental numbers, are employed as in other oratorios, but, at least in the German passion, the liturgical style controls every element; hence chorals are often introduced for the use of the congregation or audience. The most noted example is the "Passion according to St. Matthew" of J. S. Bach. Also called *passion oratorio*, or simply *passion*.

3. In *gram.*, expressive of the suffering or enduring of some action, or the being affected by some action; applied to a derivative mode of conjugation, by which that which is the object of the other or "active" form is made the subject of the enduring of the verbal action; thus, *Lydia a me amatur*, 'Lydia is loved by me,' is corresponding *passive* to *ego Lydiam amo*, 'I love Lydia.' An annual feast of the Jews, instituted to commemorate the escape of the Hebrews in Egypt, when God, smiting the houses of the Israelites, which were marked with the blood of the paschal lamb. It was celebrated on the evening of the 14th day of Abib or Nisan, the first month of the sacred year. The name is also used, by extension, to include the seven days that followed (from the 15th to the 21st of Nisan), during which the Israelites were permitted to eat only unleavened bread; and hence the *Passover* is also known as the "feast of unleavened bread." Every household with his family ate on the first evening a lamb killed by the priest (Ex. xii.), which was served up without breaking the bones.

And ye shall observe this thing for an ordinance to thee and to thy sons for ever. . . . And it shall come to pass, when your children shall say unto you, What mean ye by this service? That ye shall say, It is the sacrifice of the Lord's *passover*, who passed over the houses of the children of Israel in Egypt, when he smote the Egyptians, and delivered our houses. *Ex. xii. 24, 26, 27.*

A document issued by competent civil authority, granting permission to the person specified in it to travel, or authenticating his right to protection. In some states no person is allowed to leave the country without a pass-port from his government, but the regulations of different jurisdictions regarding the use of passports have varied much, and of late years have exhibited a tendency toward a relaxation

of stringency, extending in many countries to their total abolition. Passports must give a description of the person. Those of the United States (1887) "request all whom it may concern to permit . . . safely and freely to pass, and in case of need to give (him) all lawful Aid and Protection," and are given under the seal of the Secretary of State. Passports may be given for goods as well as for persons; and in time of war a ship's passport is a voucher of her neutral character.

The paste of common pottery is either hard or soft. The hard is that which, after firing, cannot be scratched by knife or file. In porcelain the difference is more radical, the paste of soft-paste porcelain not being strictly a ceramic production. (See *soft-paste porcelain*, under *porcelain*.) The epithets *hard* and *soft* have reference to the power of resisting heat, hard-paste porcelain supporting and requiring a much higher temperature than the other. The paste of stoneware is mingled with a vitrifiable substance, so that after being fired it is no longer porous, whereas the paste of common pottery absorbs water freely. For the *paste* operation, no leys should be used containing foreign salts.

The part of a horse's foot which corresponds to the extent of the pastern-bones, more particularly of the great pastern-bone, which occupies most of the extent between the fetlock-joint and the coronet of the hoof. This corresponds anatomically to the first phalanx of the middle finger or toe of a man's hand or foot. See *pastern bone*, and *cuts under hoof*, *fetter-bone*, *Perissodactyla*, and *solidungulate*.

I will not change my horse with any that treads but on four *pasterns*. Cu, ha! he bounds from the earth, as if his entrails were hairs. *Shak., Hen. V., iii. 7. 13.*

**pastern-bone** (pas'tern-hōn), *n.* Either one of the two proximal phalanges of a horse's foot, the first phalanx being the *great pastern*, articulated above with the cannon-bone at the pastern-joint, and the second phalanx the *small pastern*, articulated below with the third phalanx, or coffin-bone, inclosed in the hoof. These bones, great and small, correspond respectively to the first and second phalanges of the middle finger or toe of a man's hand or foot. See *cuts under hoof*, *solidungulate*, and *Perissodactyla*.

**pastern-joint** (pas'tern-jōint), *n.* The joint or articulation of a horse's foot between the great pastern-bone and the cannon-bone. Anatomically it is the metacarpo- or metatarso-phalangeal articulation, and corresponds to the joint or knuckle at the base of the middle finger or toe of a man's hand or foot. See *cuts under hoof*.

The protective or prophylactic inoculation of the attenuated virus of certain diseases, especially of hydrophobia, as devised by the French scientist Louis Pasteur (born 1822). Pasteur's method in hydrophobia consists, essentially, in progressive inoculation with less and less attenuated virus until the use of that of a high degree of intensity is attained. The virus, in its different degrees of virulency, is obtained from the spinal cord of rabid rabbits which have acquired the maximum intensity of the disease after a repeated transference of the virus from one animal to another. Sections of the cord free from foreign germs are allowed to remain, for different periods of time, in a sterilized and dry atmosphere, whereby the virulency of the virus becomes progressively diminished, until it is finally completely lost.

2. Same as *Pasturization*.

**Pasteurization** (pas-tēr-i-zā'shon), *n.* [*< Pasteur (see def.) + -ize + -ation.*] The preserving of wines or other fermented liquids from deterioration, by destroying the fungi and their spores that would be productive of further and deleterious changes. This is effected by heating the liquid to at least 140° F. Also spelled *Pasturisation*.
